# Forward Region Studies for 3 TeV CLIC

Konrad Elsener  
Linear Collider Detector Project  
CERN

## Outline:

- CLIC at 3 TeV
  - Forward Region at CLIC
  - LumiCal – a first Proposal
  - BeamCal Studies
  - Background in the Vertex Detector
  - Summary
- ( Other Issues under Study )

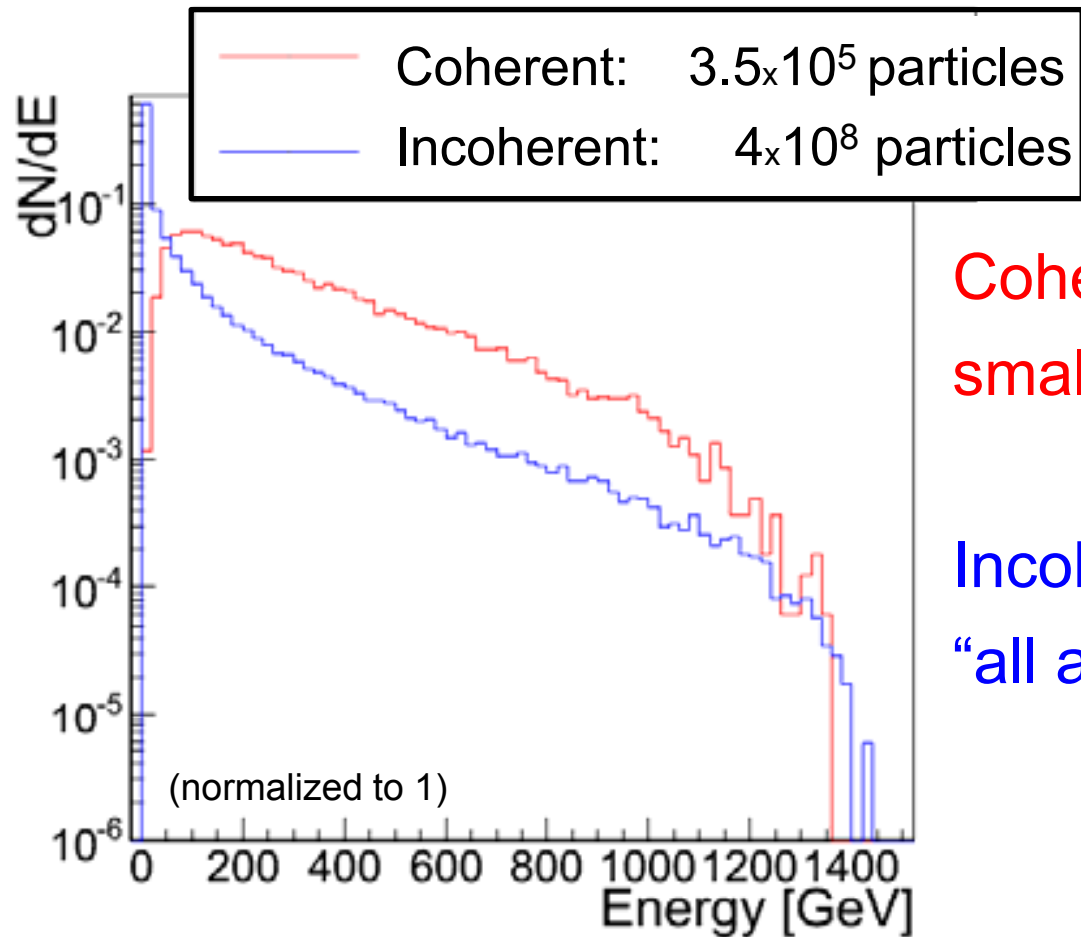

# CLIC (at 3 TeV)

- NB. Push-Pull “just as at ILC”
- 20 mrad crossing angle
- Beam-beam effect strongly enhanced: (in-) coherent pairs,  $\gamma\gamma$  -> hadron background
- Bunch spacing 0.5 ns, bunch train 156 ns, rep. rate 50 Hz -> time stamping, power pulsing etc.
- Small beam spots -> stability requirements for QD0 (and QF1)
- Crossing Angle + High Energy + Synchrotron radiation -> Luminosity Loss -> (most likely) no Anti-DiD

# Incoherent and Coherent Pairs at 3 TeV CLIC

for 1 BX

Coherent Pairs:  $6.5 \times 10^{10}$  GeV  
small angles

-> post-collision line

Incoherent Pairs:  $1.3 \times 10^7$  GeV

“all angles”

-> **background !**

## CLIC synchrotron radiation, solenoid, anti-DiD etc. ...

Work by **Barbara Dalena**, CERN (CLIC study team):

- PAC'09 contributed paper

“Solenoid and Synchrotron Radiation Effects at CLIC”

- presentation at ILC-CLIC LET Beam Dynamics Workshop, 24 June 2009

<http://indico.cern.ch/contributionDisplay.py?contribId=20&sessionId=3&confId=56133>

Map	Bz [T]	L[m]	Lumi loss [%]
Old SiD	5	2.8	~4.0
New SiD	5	2.8	~3.0
ILD	4	3.7	~4.0
ILD + AntiDiD	4	3.7	~25.0

# Forward Region at CLIC: A snapshot at today's layout

- Detector concepts based on ILD and SiD are under study
- For the forward region, so far most of the work was done on the CLIC01\_ILD concept
- For some studies, stand-alone “fast” simulations were used

(courtesy André Sailer, CERN)

## CLIC01\_ILD: Vertex and Forward Tracker

- Vertex Detector: 3 double Layers of Silicon Sensors
  - At: 31, 46, 60 mm Radius, each 25 cm long  
( $Z = \pm 12.5$  cm)
- Forward Tracking: 7 Disks
  - Inner Radius: Beam pipe
  - Outer Radius: ~30 cm (For last 5 Disks)
- Beam pipe: Conical shape up to LumiCal

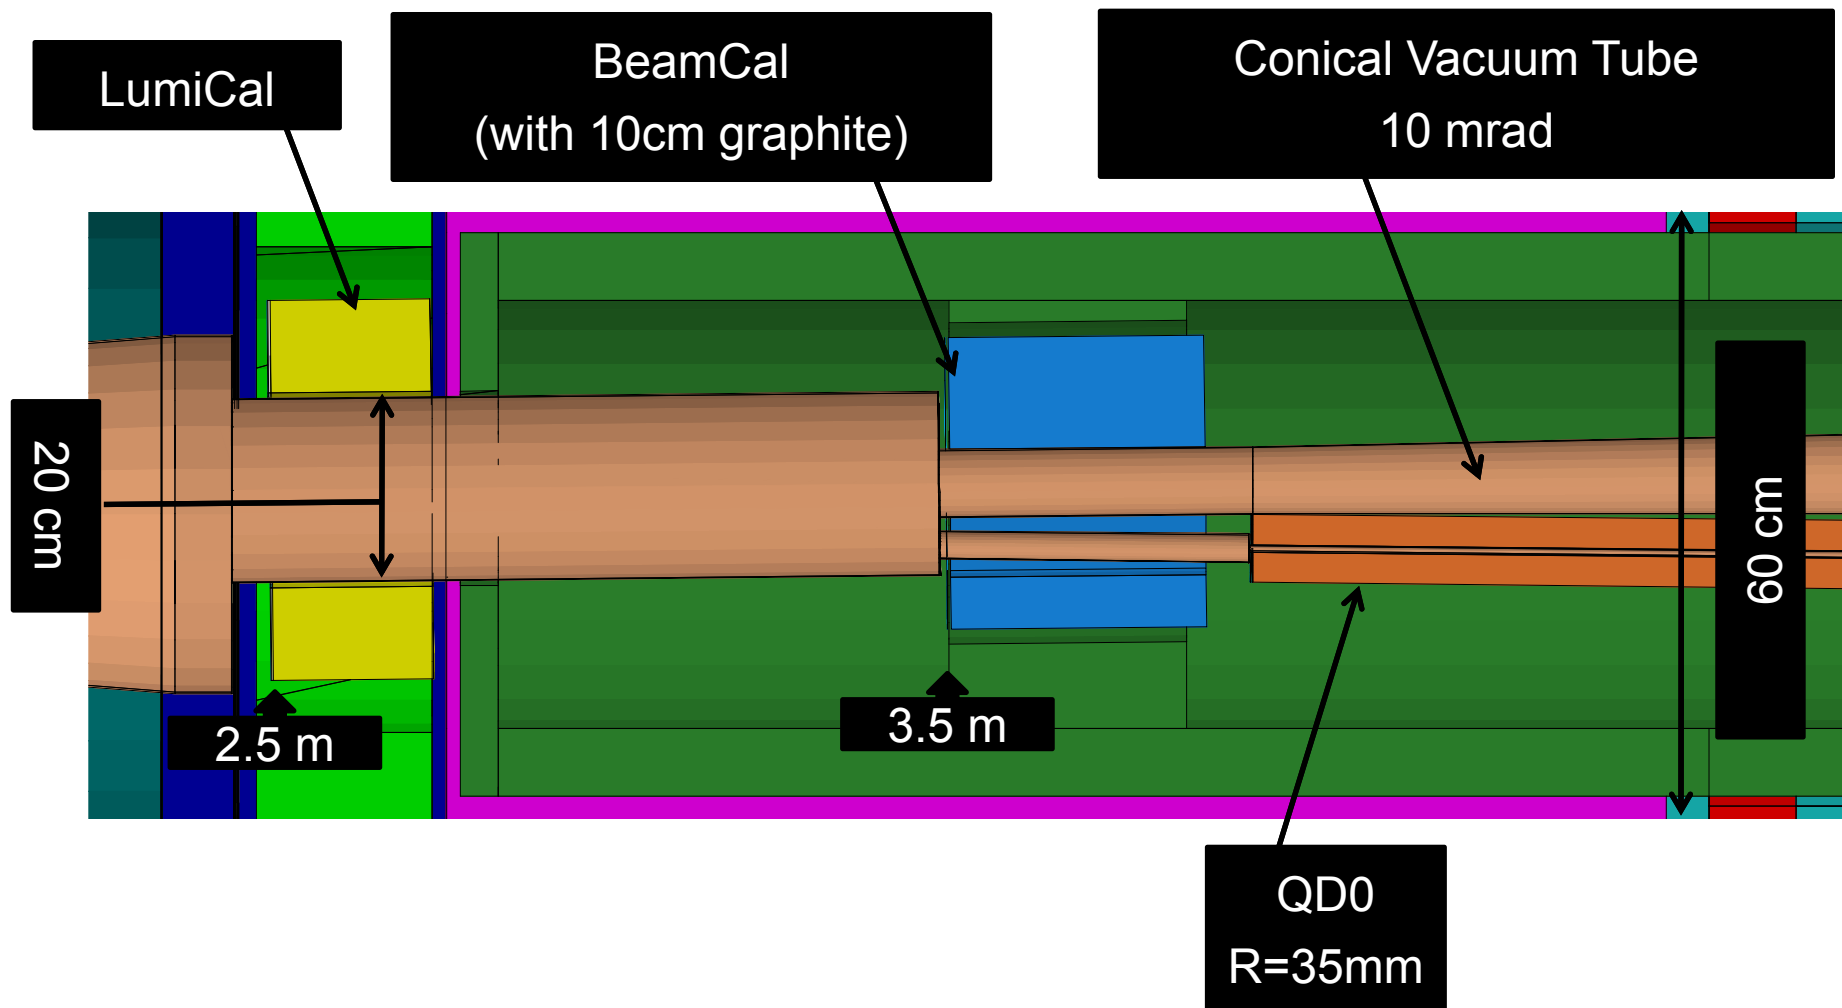

(courtesy André Sailer, CERN)

# CLIC01\_ILD: LumiCal, BeamCal and QD0

## CLIC QD0 preliminary – hybrid permanent / warm e.m. magnet

# LumiCal – a first proposal

(courtesy Iftach Sadeh, Tel Aviv Univ.)

LumiCal – a first proposal

(courtesy Iftach Sadeh, Tel Aviv Univ.)

## LumiCal Parameters (present status):

Design Goal: 1% accuracy for Luminosity Measurement

Distance (front-face) from IP: 2.27 m (-> 2.5 m for CLIC01\_ILD)

Inner Radius geometric: 10 cm (44 mrad)      fiducial: 50 mrad

Outer Radius geometric: 35 cm (153 mrad)      fiducial: 130 mrad

Passive Layers: 3.5 mm W

Active Layers: Si (total space: 1 mm between W layers)

Radial Divisions: 50

Azimuthal Divisions: 48

dynamic range of signals (MIP->max.): 4 fC to 50 pC

Number of Layers: 40

Bhabha event rate:  $4 \times 10^6$  / year (50% selection efficiency,  $10^7$  s)

LumiCal – a first proposal  
(courtesy Iftach Sadeh, Tel Aviv Univ.)

... Similarities with ILC LumiCal ...

Hamamatsu  
S10938-8380

LumiCal – a first proposal  
 (courtesy Iftach Sadeh, Tel Aviv Univ.)

## CLIC LumiCal Issue: Background (incoherent pairs)

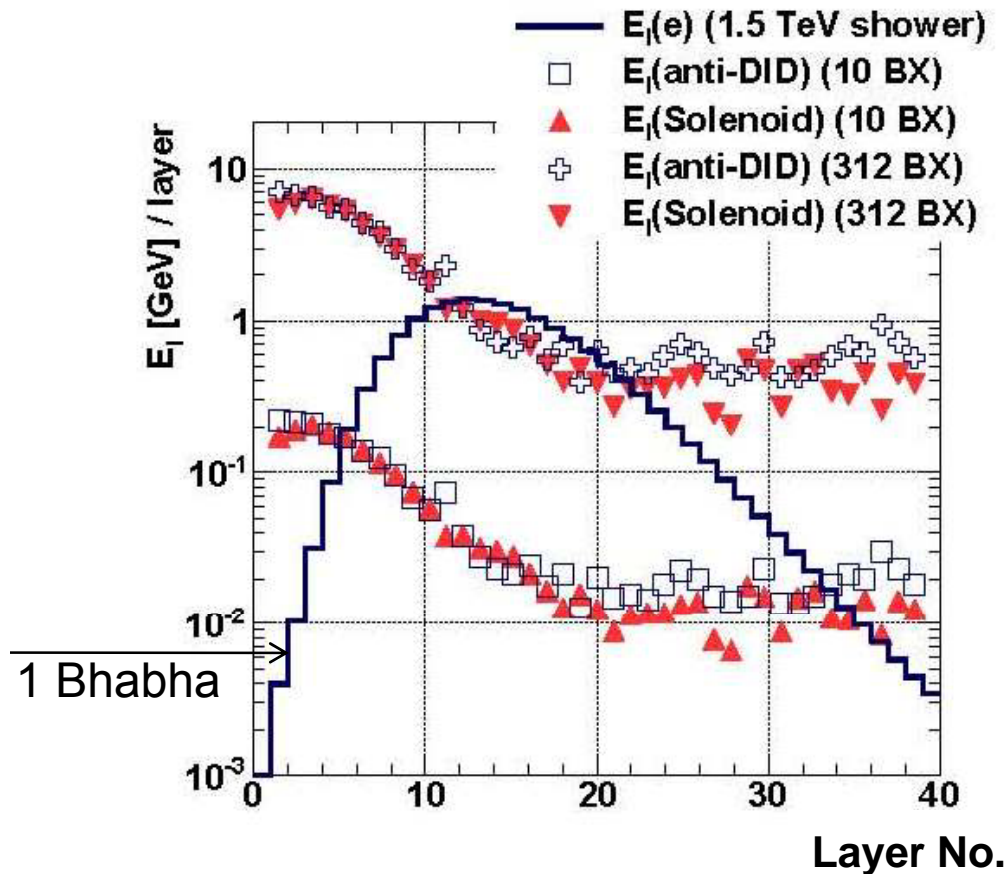

- Solenoid field (no anti-DiD)
- Integrated over 10 BX

LumiCal – a first proposal  
(courtesy Iftach Sadeh, Tel Aviv Univ.)

## CLIC LumiCal Issue: Background (incoherent pairs)

- this plot for  $R_{\min} = 10$  cm
- **exaggerated / pessimistic**  
Bhabha events are “local”,  
background is total LumiCal

LumiCal – a first proposal

## CLIC LumiCal: work in progress

- topological cuts (“clustering”) to reduce background
- time-stamping layer needed ? (resolution ?)
- dynamic range of readout electronics  $> 10^4$ 
  - feasible? switching range for MIP calibration ?
- physics background and selection cuts
  - models: WHIZARD vs. BDK
  - beam-beam and Bhabha Suppression Effect,  
and influence on selection cuts
- ...

# BeamCal Studies

(courtesy André Sailer, CERN)

## BeamCal Studies

(courtesy André Sailer, CERN)

## BeamCal Parameters (present status):

Distance (front-face) from IP: 3.2 m

Inner Radius : 2.6 cm (8 mrad)

Outer Radius : 15 cm (46 mrad)

Passive Layers: 3.5 mm W

Active Layers: Si (for the purpose of simulations –  
will need radiation hard detectors)

Number of Layers: 40

## Study high energy electron signal vs. background

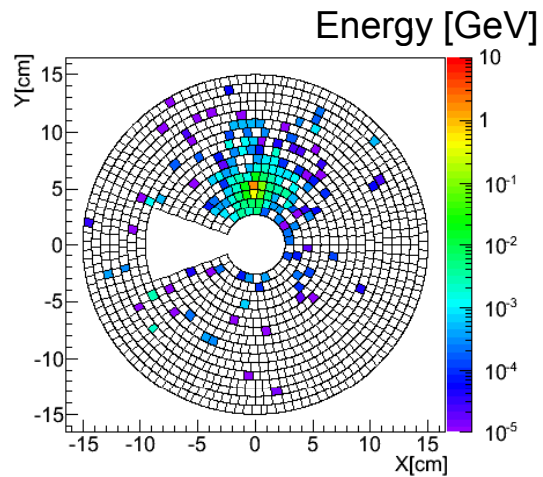

## BeamCal Studies

(courtesy André Sailer, CERN)

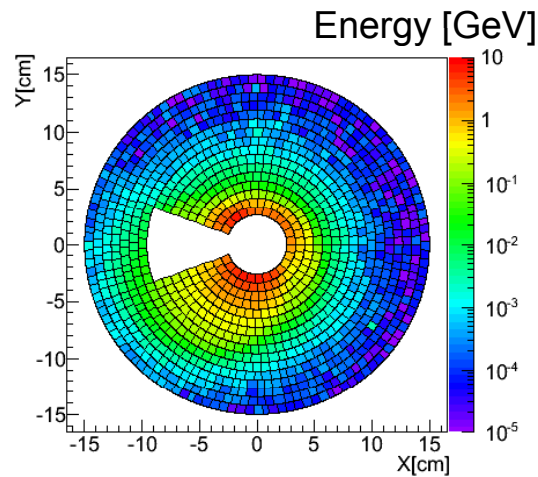

# Preliminary “quick test” of h.e. Electron identification in BeamCal

Example: 1500 GeV electron hitting at 19 mrad  
background particles from 1 BX shown

background particles from 1 BX shown

Layer 38

Layer 38

## BeamCal Studies

(courtesy André Sailer, CERN)

# Preliminary “quick test” of h.e. Electron identification in BeamCal

- For each Pad of BeamCal
  - record deposited energy from 1.5 TeV electrons
  - record deposited energy fluctuation from background (for the given number of BX)
  - **sum up the energies**  $E_{e,i} > \max \{ \langle E_{bg} \rangle - E_{bg,i} \}$   
from those pads in which the deposited energy from the h.e. electron is **larger than the fluctuation** (for the given number of BX)
- “Quality of Signal”:  
**sum of energy above fluctuation /**  
total deposited energy from the high energy electron

## BeamCal Studies

(courtesy André Sailer, CERN)

# A 1500 GeV electron at 12 mrad and background from 1 BX

Total Background 1 BX

Energy above Fluctuation

1500 GeV Electron at 12 mrad

## BeamCal Studies

(courtesy André Sailer, CERN)

# A 1500 GeV electron at **26 mrad** and background from 312 BX

Total Background 312 BX

Energy above Fluctuation

1500 GeV Electron at 26 mrad

## BeamCal Studies

(courtesy André Sailer, CERN)

# “Quality of Signal” as function of electron impact angle

- 1500 GeV electrons
- 1 BX Background
- fiducial volume goes up to 40 mrad
- leakage for larger angles

## BeamCal Studies

# “Quality of Signal” as function of electron impact angle

## 156 BX

Integrated BX: 156, Limit 1 Sigma Coh 1500GeV

## 312 BX

Integrated BX: 312, Limit 1 Sigma Coh 1500GeV

## BeamCal Studies

(courtesy André Sailer, CERN)

### Summary of BeamCal Issues – very preliminary

- work in progress – more detailed studies needed on
  - use of BeamCal for h.e. electron identification / veto at small angles: need improved method  
(cf. work by Gleb Oleinik, Colorado)
  - checking use of BeamCal for beam diagnostics
  - angular coverage and masking
- need for time-stamping to improve electron identification

# Background in the Vertex Detector

(courtesy André Sailer, CERN)

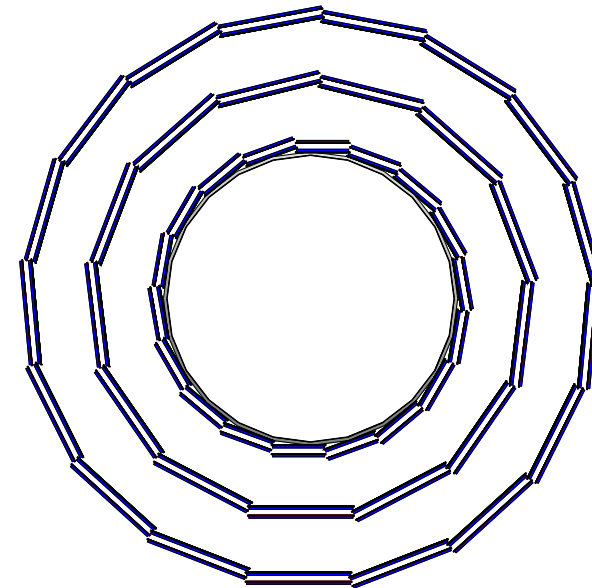

Background in the Vertex Detector  
(courtesy André Sailer, CERN)

- CLIC01\_ILD
- Vertex Detector
  - 3 double Layers at  $R=31/45/60\text{mm}$
  - All layers 25 cm long
  - 50  $\mu\text{m}$  active Silicon
  - Threshold: 3.4 keV
- 4 T Solenoid Field

(Hadronic Calorimeter

- $8.5\lambda$
- Absorber: Tungsten, 1cm thick, 77 layers)

## Background hits in whole Vertex detector, per BX (no anti-DID)

Origin of particle	first CLIC model	latest model
IP	1030	874
LumiCal	0	0
BeamCal	727	474
QD0	101	129
Vacuum Tube	7482	1029
<b>Total</b>	<b>9341</b>	<b>2505</b>

On innermost vertex double layer: **1.9 Hits / cm<sup>2</sup> / BX**

Background in the Vertex Detector  
(courtesy André Sailer, CERN)

## Summary of Background in Vertex Issues

- innermost vertex (double-)layer at 31 mm  
(avoid direct hits from incoherent pairs)
- much progress made to reduce backscattering into vertex
- additional difficulties since we have no Anti-DiD field
- number of hits **per BX** in the innermost vertex detector layer  
now comparable to ILC
- need time-stamping to avoid accumulation of BG hits

# Summary

- Forward region at 3 TeV CLIC: significant progress in 6 months  
many thanks to FCAL collaboration for support,  
thanks to ILD and SiD for software and much input
- clear path towards a LumiCal (but more studies needed concerning topological cuts and - possibly - time stamping)
- BeamCal looks difficult, even with good time stamping – work needed to understand physics reach if electron veto is only o.k. at angles, e.g., larger than 15 mrad
- Background in vertex detector appears under control (as long as time stamping is used)
- **Work in progress – thank you for your attention !**

## Other Studies w.r.t. “forward” + “MDI”

- New MDI chair at CERN: Lau Gagnon – MDI priority on QD0 design and stabilisation
- Phil Burrows et al. (Oxford): intrabeam feedback (based on FONT experience)
- Rob Appleby, Mike Salt et al. (Cockcroft): gamma (and neutron) background in detector due to backscattering from post-collision line
- LCD Project Team at CERN: Physics Case for a longer barrel (aspect ratio)
- Ivanka Bozovic-Jelisavcic et al. (Belgrade): BHSE and systematic errors in LumiCal, Physics background, differences between Whizard and BDK
- Barbara Dalena, Detlev Svoboda (CERN): anti-solenoid coils (improve optics, shield QD0 against main solenoid field)
- Alain Herve (ETH Zurich): support QD0 independently of the detector, push-pull, etc.
- Hubert Gerwig (CERN): reduce the amount of iron in the yoke ... (hybrid yoke+coils)
- Claude Hauviller et al.: vibration measurement in LHC tunnel on either side of LHCb; vibration measurements on the floor and on top of CMS
- Hermann Schmickler (CERN): measure nm vibration of a quadrupole by observing the beam
- Annecy+CERN: stabilisation of CLIC modules and FF quadrupole
- ...

# SPARE SLIDES

Source :

K. Wichmann (DESY)

ILD Detector Optimisation

WG Phone Meeting

13 May 2009

# CLIC time structure

Train repetition rate 50 Hz

**CLIC:** 1 train = 312 bunches

0.5 ns apart

50 Hz

**ILC:** 1 train = 2820 bunches

308 ns apart

5 Hz

## Consequences for CLIC detector:

- Need for detection layers with **time-stamping**
  - Inner-most tracker layer with ~ns resolution
  - or .... all-detector time stamping at the 10 ns (?) level
- Readout/DAQ electronics will be different from ILC
  - Power pulsing has to work at **50 Hz** instead of 5 Hz

# CLIC 3 TeV Beam-induced background

## Backgrounds:

Due to the higher beam energy and small bunch sizes backgrounds are significantly more severe at CLIC.

## Main backgrounds:

- CLIC 3TeV beamstrahlung average energy loss: **29%** ( $10 \times ILC_{\text{value}}$ )
  - **Coherent pairs** ( $3.8 \times 10^8$  per bunch crossing)  $\Leftarrow$  disappear in beam pipe
  - **Incoherent pairs** ( $3.0 \times 10^5$  per bunch crossing)  $\Leftarrow$  suppressed by strong solenoid-field
  - $\gamma\gamma$  interactions  $\Rightarrow$  hadrons ( $\approx$  **3 hadron events per bunch crossing**)
- Muon background from upstream linac
  - More difficult to stop due to higher CLIC energy (active muon shield ?)

# CLIC 3 TeV centre-of-mass energy spectrum

## Due to beam-beam effects:

- At 3 TeV only 1/3 of the luminosity is in the top 1% centre-of-mass energy bin
- asymmetric situation -> many events with large forward / backward boost

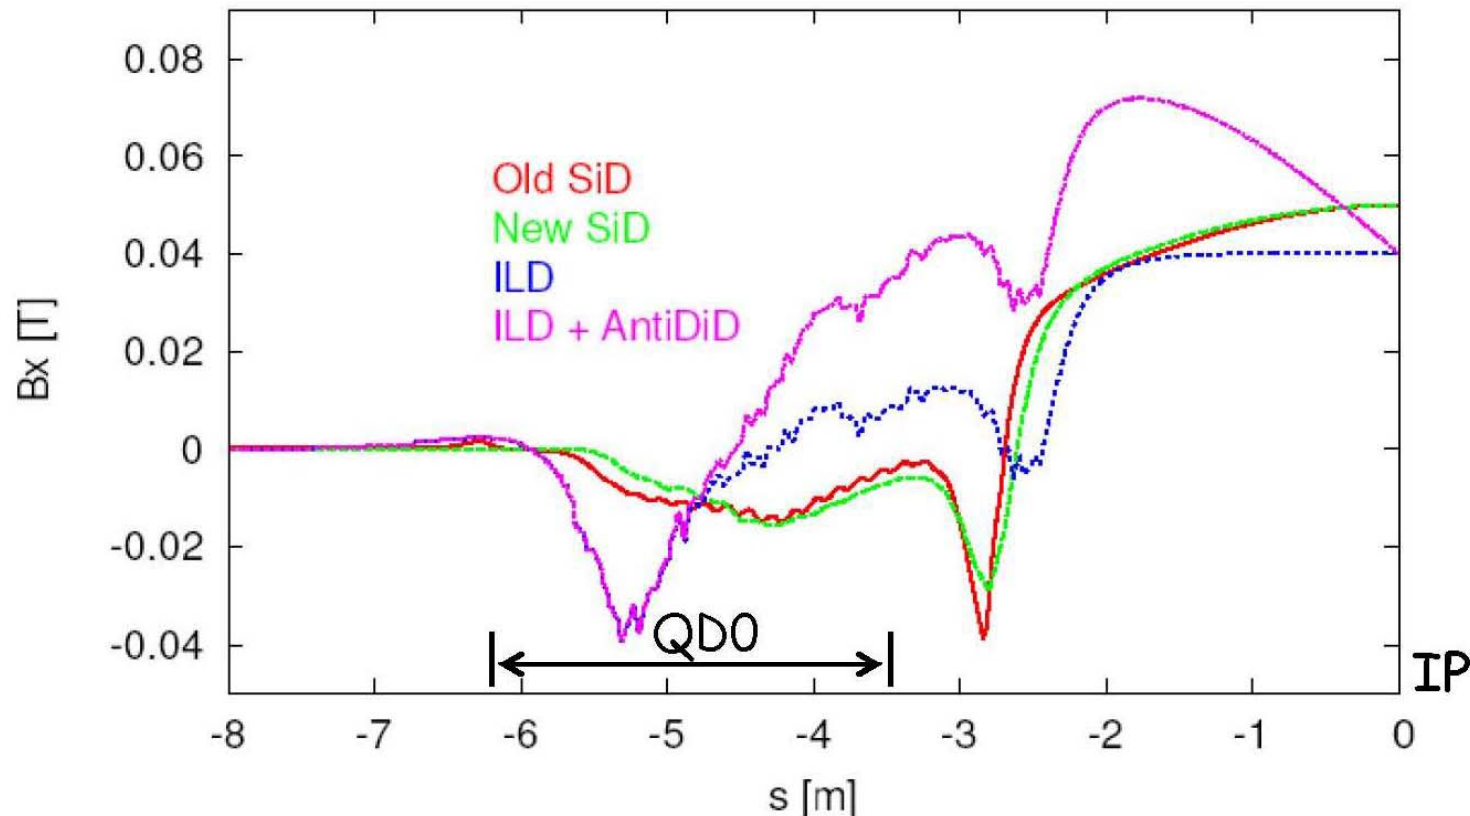

# CLIC synchrotron radiation, solenoid, anti-DiD etc. ...

Work by **Barbara Dalena**, CERN (CLIC study team):

Fields Acting on Y (incoming electron)

**CLIC**  
**20 mrad**

$B_x$  component of solenoid fields in the beamline reference system

# Track Occupancy from $\gamma\gamma$ Background

## VXD

	R=30 mm	R=50 mm	R=70 mm
	$-50 < z < 50 \text{ mm}$	$-125 < z < 125 \text{ mm}$	$-125 < z < 125 \text{ mm}$
Hits/mm <sup>2</sup> /Train	$\sim 0.20$	$\sim 0.17$	$\sim 0.14$

## FTD

	$z = 200 \text{ mm}$
	$85 < R < 140 \text{ mm}$
Hits/mm <sup>2</sup> /Train	$\sim 0.04$

- $\gamma\gamma \rightarrow$  hadron background affects mostly channels with missing energy or precise di-jet mass reconstruction because of extra energy injected in the event;
- occupancy appears negligible in Barrel Cal and modest in Vertex tracking with time stamping  $\sim 10\text{-}20$  ns, preliminary results documented in CLIC Note in preparation;
- optimisation of time stamping strategy (very precise timing at a single layer or distributed timing in innermost tracking layers) requires to consider constraints from layer material budget, power dissipation and pixel sizes.
- study pattern recognition efficiency and performance for different VXD concepts (in collaboration with Alex Kluge et al.) on physics benchmarks  
+  $\gamma\gamma \rightarrow$  hadrons and PAIR background.

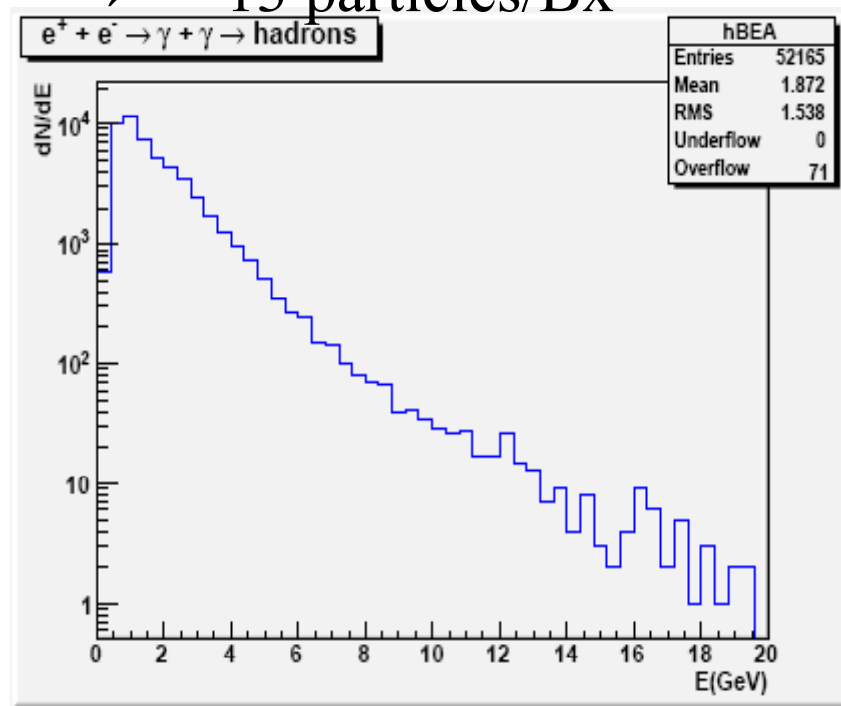

Marco Battaglia, LCD meeting,  
CERN, 19 May 2009

$$e^+ + e^- \rightarrow \gamma \gamma \rightarrow \text{hadrons}$$

At 3 TeV  $\sim 3.3$   $e^+ + e^- \rightarrow \gamma \gamma \rightarrow \text{hadrons}$  events / Bx

$\rightarrow \sim 13$  particles/Bx

$\langle E_h \rangle \sim 1.9$  GeV

GeV.

$\langle Pt \rangle \sim 0.9$

# $e^+ + e^- \rightarrow \gamma \gamma \rightarrow \text{hadrons}$

Background peaked in F/B region.

Fig1:  $dE/d\theta$  for 10 ns time window

Energy deposit in a  $10^\circ$  cone:

- $\sim 20$  GeV in barrel region
- $\sim 200$  GeV in F/B regions
- $\sim 7.5$  TeV per train in the detector.

Time stamping is essential.

Fig2:  $dN/d\theta$  for 10 ns time window

Occupancy/train/cm<sup>2</sup> at 2m

- $\sim 0.08$  in barrel region
- $\sim 0.3$  in F/B regions

May be an issue for HCAI if cells  $\gg 1$  cm<sup>2</sup>.
