

Short Status of TB Analyses in SDHCAL

Imad Laktineh

Progress in the SDHCAL analysis

- Mini-SDHCAL
 - Standard GRPC
 - High-Rate GRPC
- 1 m² performance study

Mini-SDHCAL

(2008-2009)

4+1 GRPCs

Each equipped with 4 HR1
($4 \times 8 \times 8 = 256$ ch)

→ 4 standard GRPCs

(Float glass, graphite painting)

→ 1 GRPC :

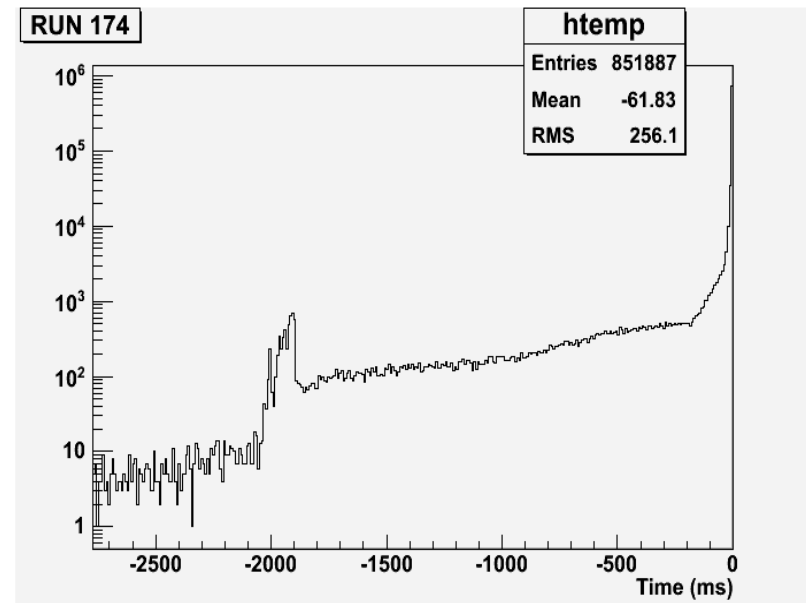

* Different paintings

* Semi-conductive glass

→ Trigger system :

2 PM-scintillators

External trigger → read recorded events and sort them out according to their time stamp % trigger

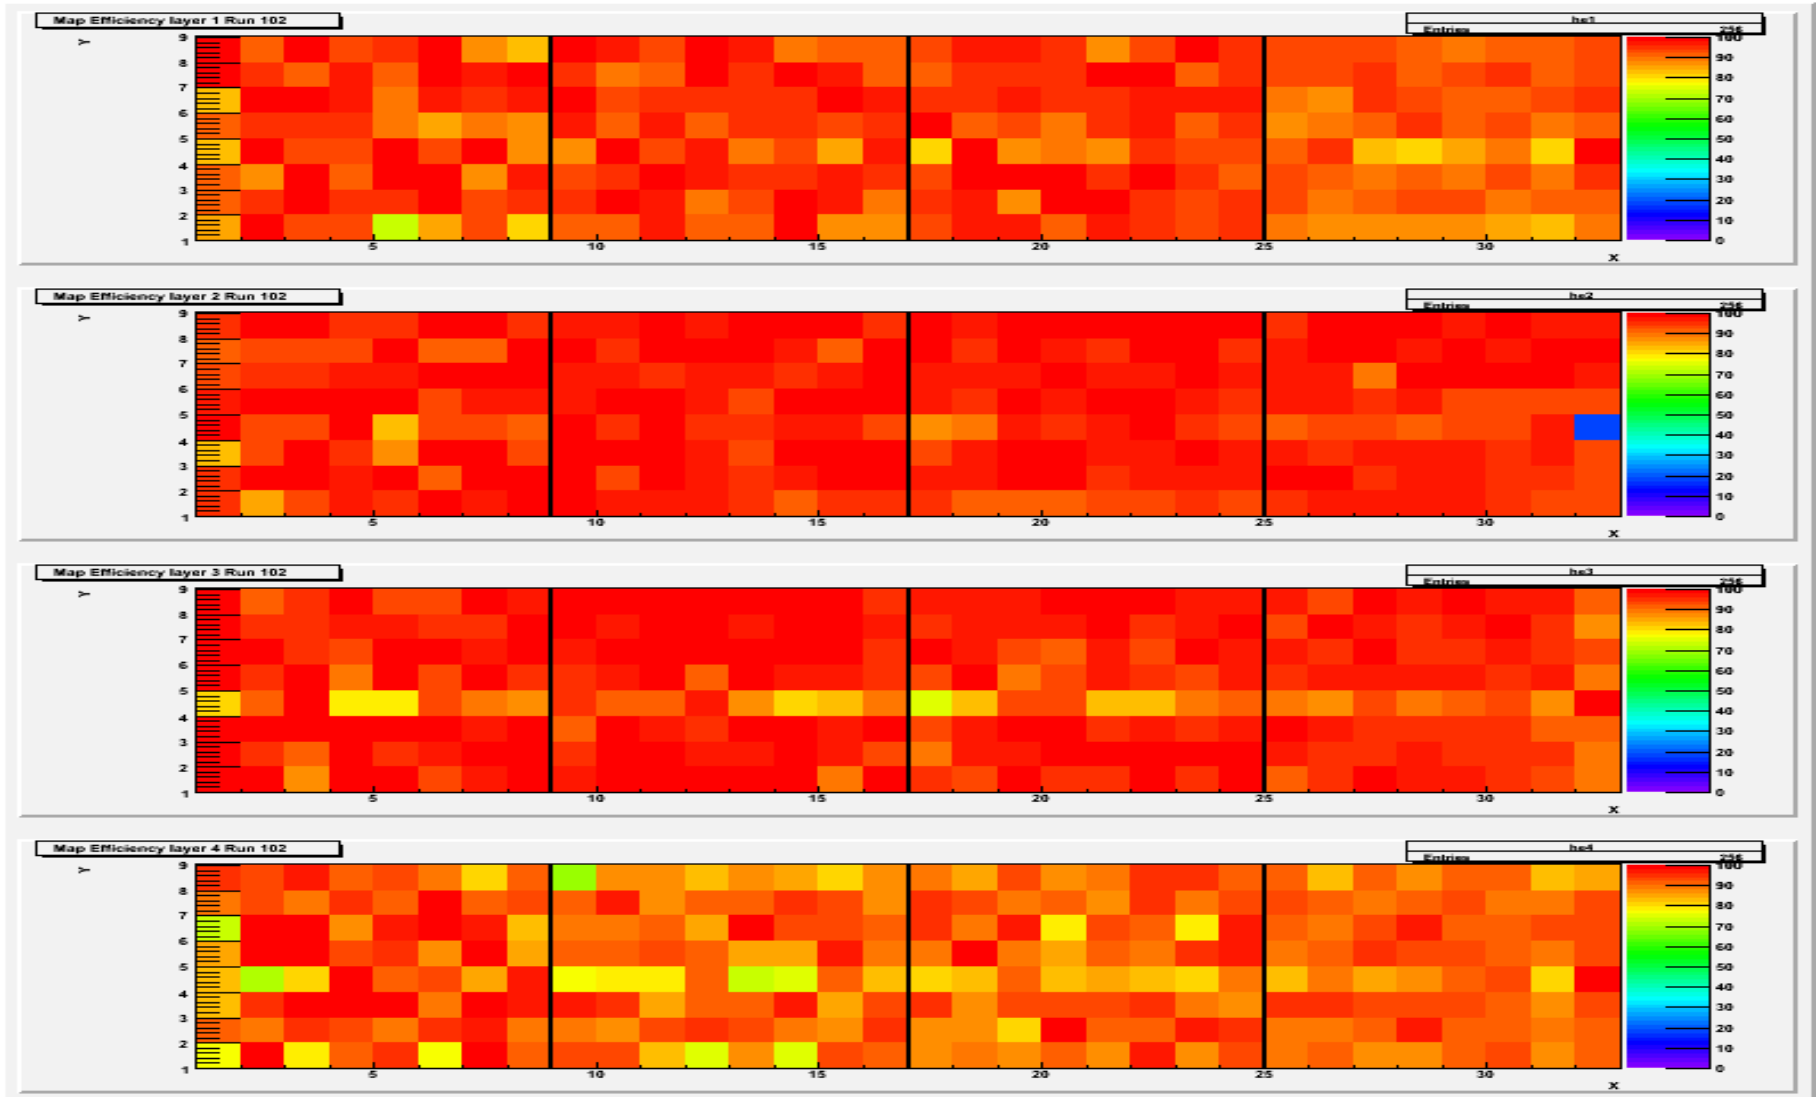

Principle :

To study one of the GRPCs, tracks are made of the hits belonging to the other GRPCs are built and projected on the studied one → efficiency and multiplicity

Uniformity of the GRPCs response (RUN 102, HV =7;4 kV)

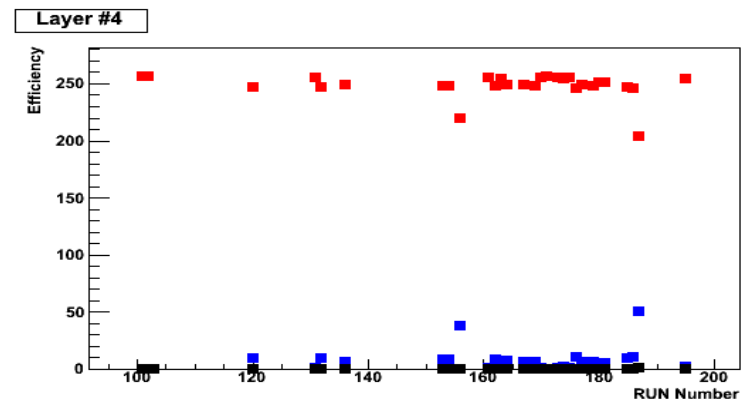

Stability of Efficiency in time

Efficient cells: $\text{Eff} > 65\%$

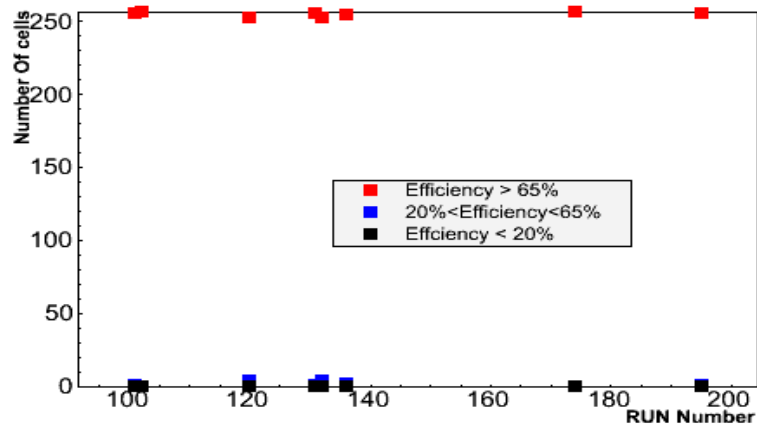

Medium cells: $20\% < \text{Eff} < 65\%$

Dead cells: $\text{Eff} < 20\%$

All high-voltage values

Layer #1

Layer #2

Layer #3

Layer #4

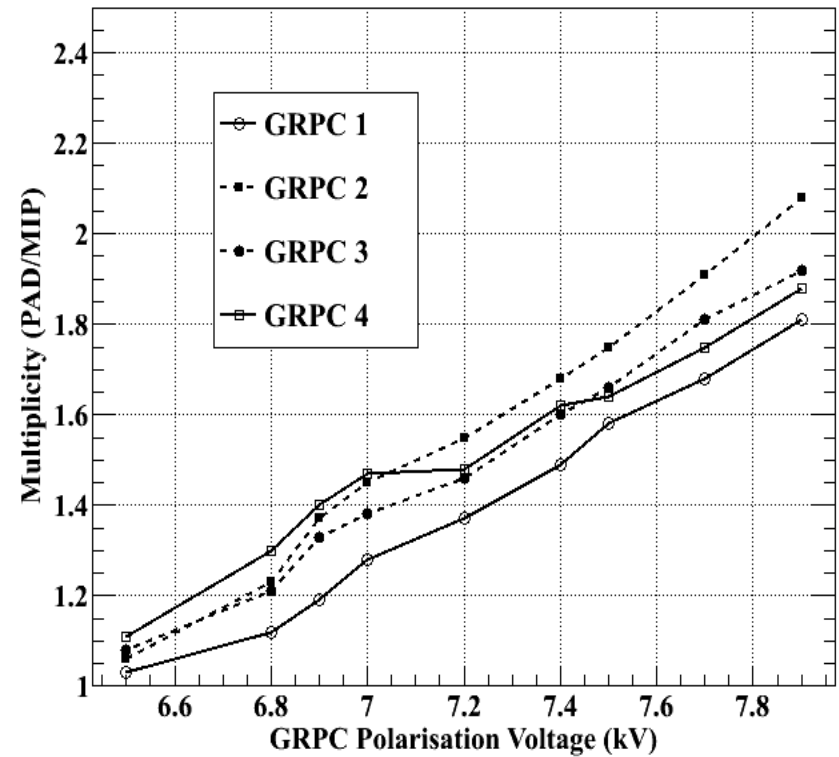

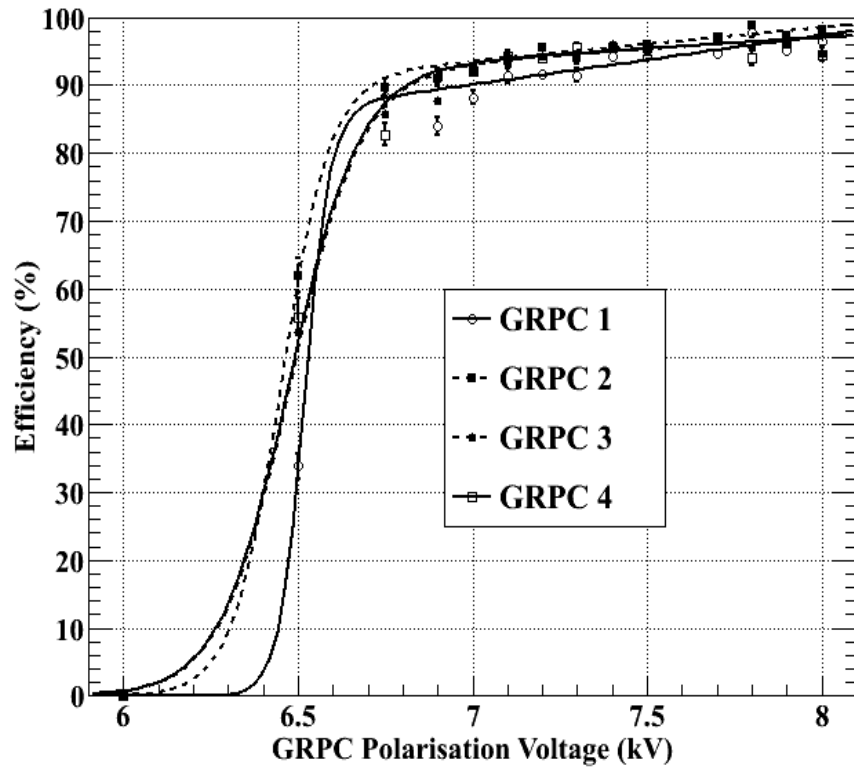

Only 7.4 kV

Stability of Multiplicity in time

Results with standard GRPCs

GRPCs Comparison

Efficiency Vs Hight Voltage (Gas mix: Isobutane/TFE/SF6)

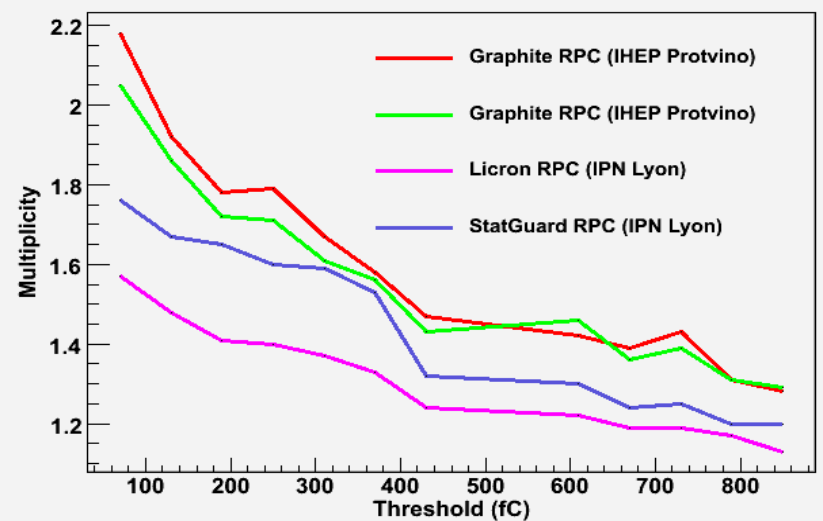

Multiplicity Vs Hight Voltage (Gas mix: Isobutane/TFE/SF6)

Efficiency Vs Threshold

Multiplicity Vs Threshold.

GRPCs Comparison

Performance of high rate GRPC

Semi-conductive glass resistivity $10^{10} \Omega \cdot \text{cm}$ to be compared with $10^{13} \Omega \cdot \text{cm}$ for float (standard) glass

50X50 cm² glass plates are being produced for SDHCAL

Hadronic showers

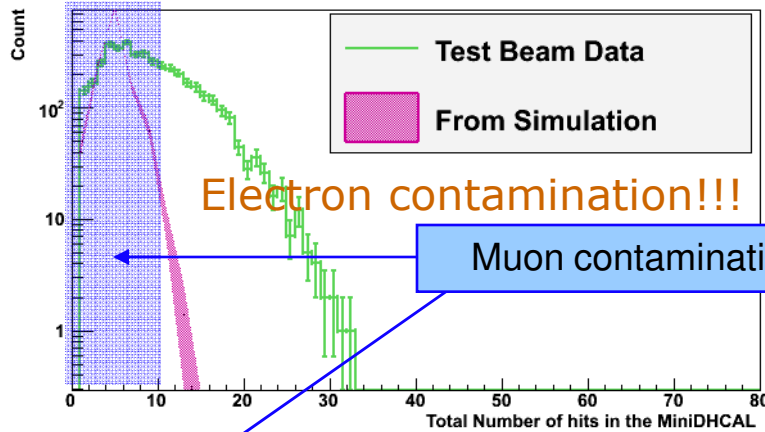

Comparison data/simulation of shower development, and energy deposition in the mini SDHCAL

Muon contamination area

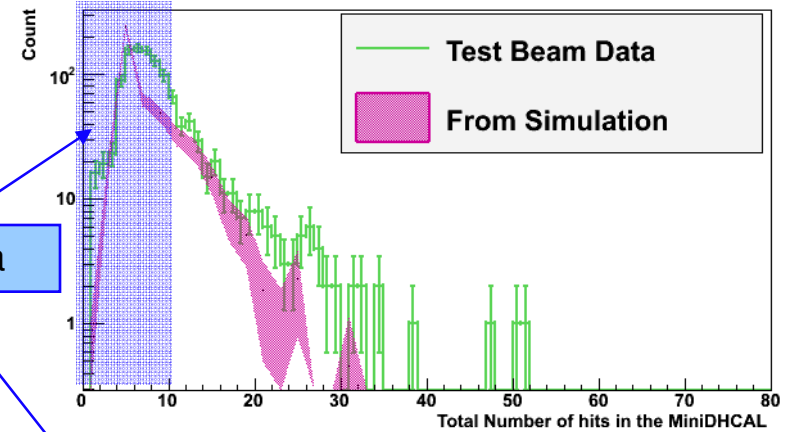

Hadronic showers Vs Simulation

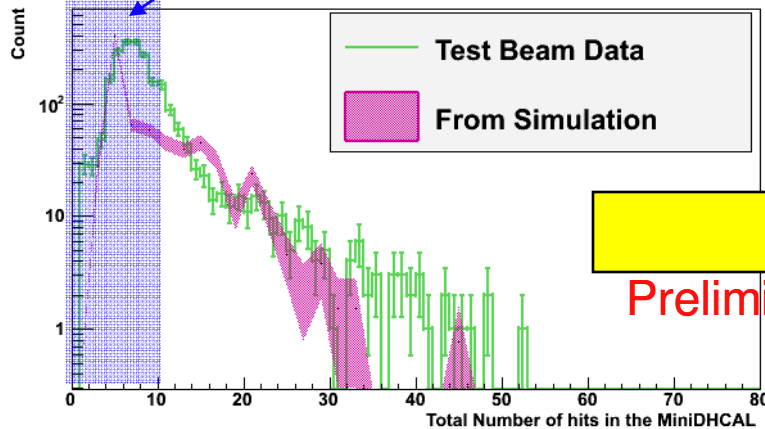

1GeV Pions (Threshold 220 DAQ = 160 fC)

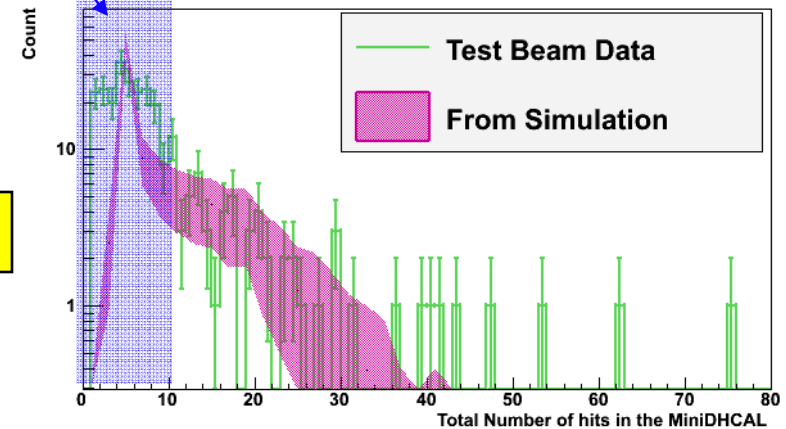

3GeV Pions (Threshold 220 DAQ = 160 fC)

5GeV Pions (Threshold 220 DAQ = 160 fC)

6GeV Pions (Threshold 220 DAQ = 160 fC)

Distribution of **hit's total number** in mini SDHCAL for test beam data and geant4 simulated data.

1M² study

Although the whole system (Detector+ Electronics + DAQ) worked perfectly well the first two days of the TB@SPS (2009) The problem with connectors made it difficult to exploit data taken afterwards.

After replacing connectors: a new system was conceived in Lab.

- PM-scintillator trigger
- Build tracks from associated hits from mini-SDHCAL
- Project on the big chamber and look if any hits

Small Setup

Synchronization between the two systems is guaranteed by Xdaq

Cosmic signal time distribution

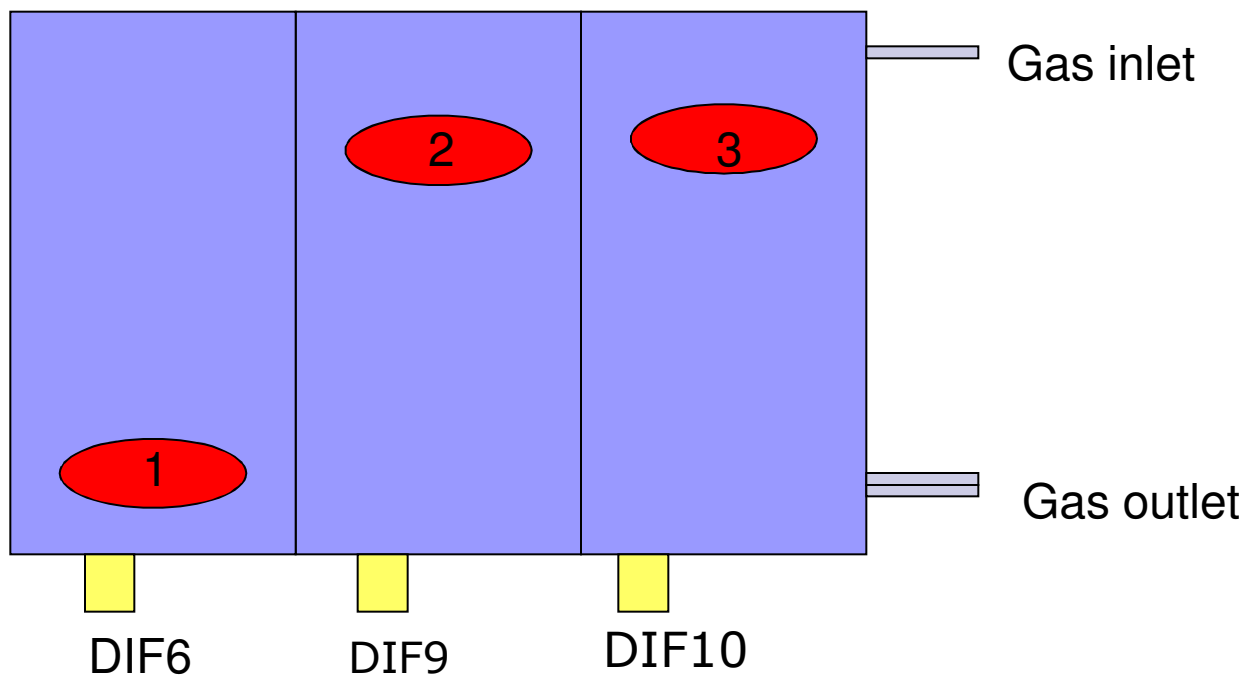

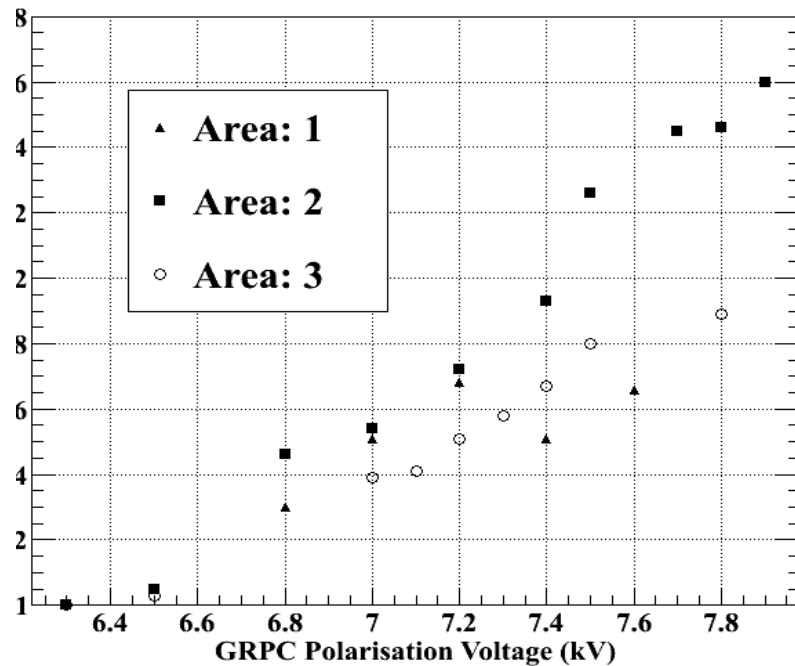

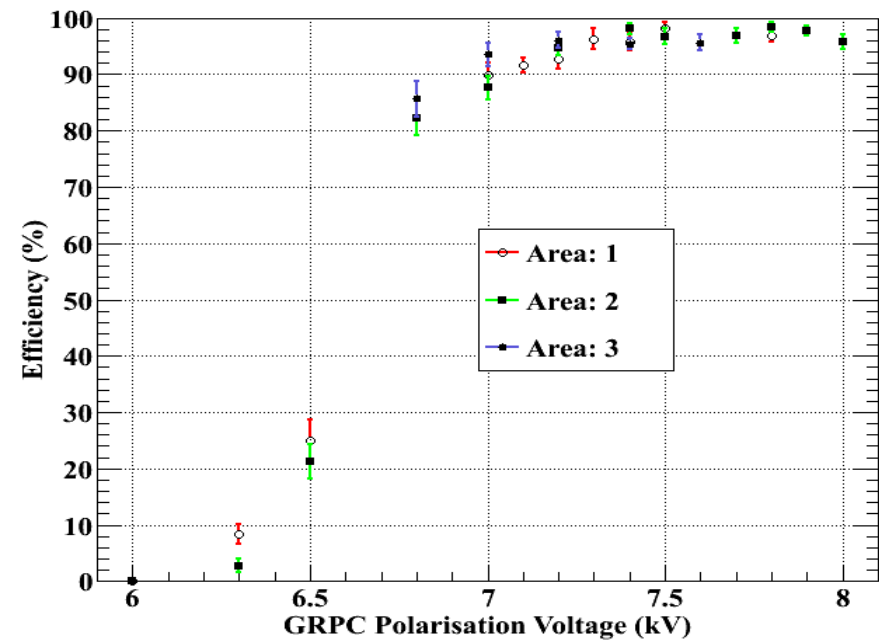

Trigger time ref.

Measured noise at 7.4 kV is $< 1.5 \text{ Hz/cm}^2$
but should be improved when the gain correction is applied
and the detector inserted in the metallic cassette

Distance between expected and found clusters

Ongoing measurements.....

Those results are obtained **without gain correction** and at different moments (different T,P,H...)

DIF6_3 1	DIF9_3 2	DIF10_3 3
DIF6_2 4	DIF9_2 5	DIF10_2 6
DIF6_1 7	DIF9_1 8	DIF10_1 9

The study is currently ongoing with gain correction.
T,P,H are also being measured

Conclusion

Test Beam with mini-SDHCAL was very fruitful and an important part of data was analyzed.

Test Beam with large GRPC was very useful. This allowed to understand real life problems.

New setup combining both small GRPCs and large one allows to study efficiently the characteristics of the large detector system.

Online acquisition system enables one to follow the evolution of data taking and understand the problem.

Two additional large GRPCs, fully equipped are being assembled and will be exposed to TB in May. This is going to be an exciting moment
