

# Improving Prompt EM Energy Component of Jet Energy Resolution with $\pi^0$ Fitting

Brian van Doren  
University of Kansas  
LCWS11  
29 Sep 2011

# Outline

- Previous Single  $\pi^0$  Study
- Multiple  $\pi^0$ 's Using Truth Information
  - $Z^0$  Study
- Reconstruction without Truth Information
  - Procedure
  - Matching Algorithms
  - Performance
- Conclusion and Future Work

# The Software Environment

- Generation:  $\pi^0$  4-Vectors towards the barrel of ILD\_00  
 $45^\circ < \theta < 135^\circ$
- Simulation: MOKKA – Geant4  
ilcsoft v01-09
- Reconstruction: Marlin framework
  - 1) Pandora Particle Flow Analysis
    - Reconstruction of 4-vectors of all visible particles
    - Identification of particle (photon, electron, neutron, etc...)
  - 2)  $\pi^0$  mass constrained fitting using MarlinKinFit
    - Implemented as a Pandora algorithm

# Mass Constrained Fit

- A quick reminder...

Given process  $\pi^0 \rightarrow \gamma_1 + \gamma_2$

We apply mass of  $\pi^0$  as constraint C. Then minimize S by adjusting  $\mathbf{x}^f$  subject to C.

$$C = (p_{\gamma_1} + p_{\gamma_2})^2 - m_{\pi^0}^2 = 0 \quad S = \sum \left( \frac{x_i^{(m)} - x_i^{(f)}}{\sigma_i} \right)^2$$

Our case using E,  $\theta$ ,  $\phi$

$$S = \left( \frac{E_1^{(m)} - E_1^{(f)}}{\sigma_{E1}} \right)^2 + \left( \frac{\theta_1^{(m)} - \theta_1^{(f)}}{\sigma_{\theta1}} \right)^2 + \left( \frac{\phi_1^{(m)} - \phi_1^{(f)}}{\sigma_{\phi1}} \right)^2 + \left( \frac{E_2^{(m)} - E_2^{(f)}}{\sigma_{E2}} \right)^2 + \left( \frac{\theta_2^{(m)} - \theta_2^{(f)}}{\sigma_{\theta2}} \right)^2 + \left( \frac{\phi_2^{(m)} - \phi_2^{(f)}}{\sigma_{\phi2}} \right)^2$$

$$C = (p_{\gamma_1}^{(0)} + p_{\gamma_2}^{(0)})^2 - (p_{\gamma_1}^{(1)} + p_{\gamma_2}^{(1)})^2 - (p_{\gamma_1}^{(2)} + p_{\gamma_2}^{(2)})^2 - (p_{\gamma_1}^{(3)} + p_{\gamma_2}^{(3)})^2 - m_{\pi^0}^2 = 0$$

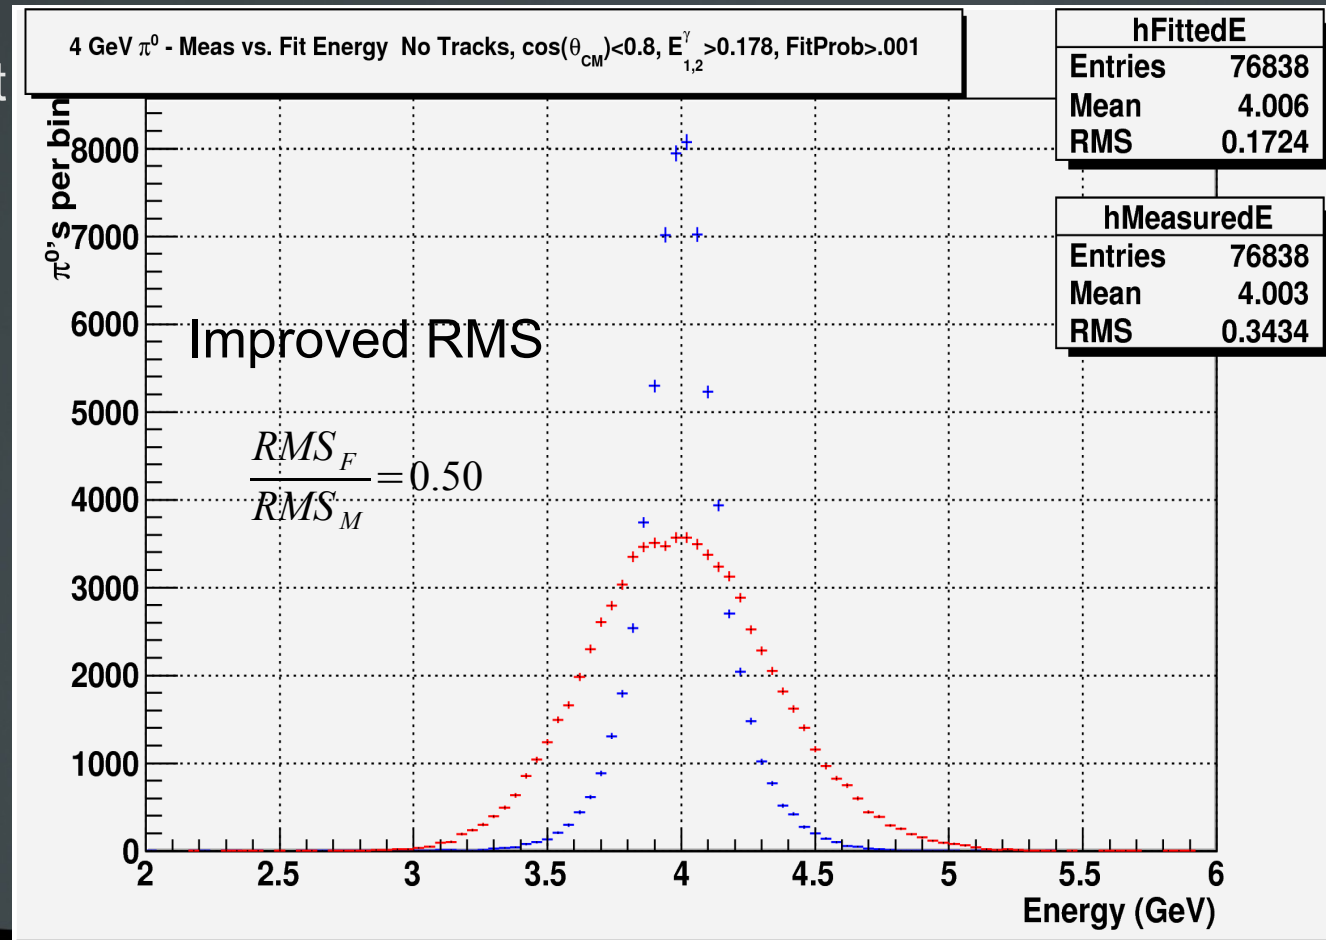

# 4.0 GeV $\pi^0$ Mass Constrained Fits

- Single  $\pi^0$  in ILD\_00 towards the barrel
- Efficiency of  $\cos(\theta_{C_M})$  cut: 84%

Relative to  $\cos(\theta_{C_M})$  cut

No Tracks	92%
Fit Prob >.001	98%
Low E Cut	99%
Combined	91%

Overall efficiency  
is 77%

# Fitting Multiple $\pi^0$ 's

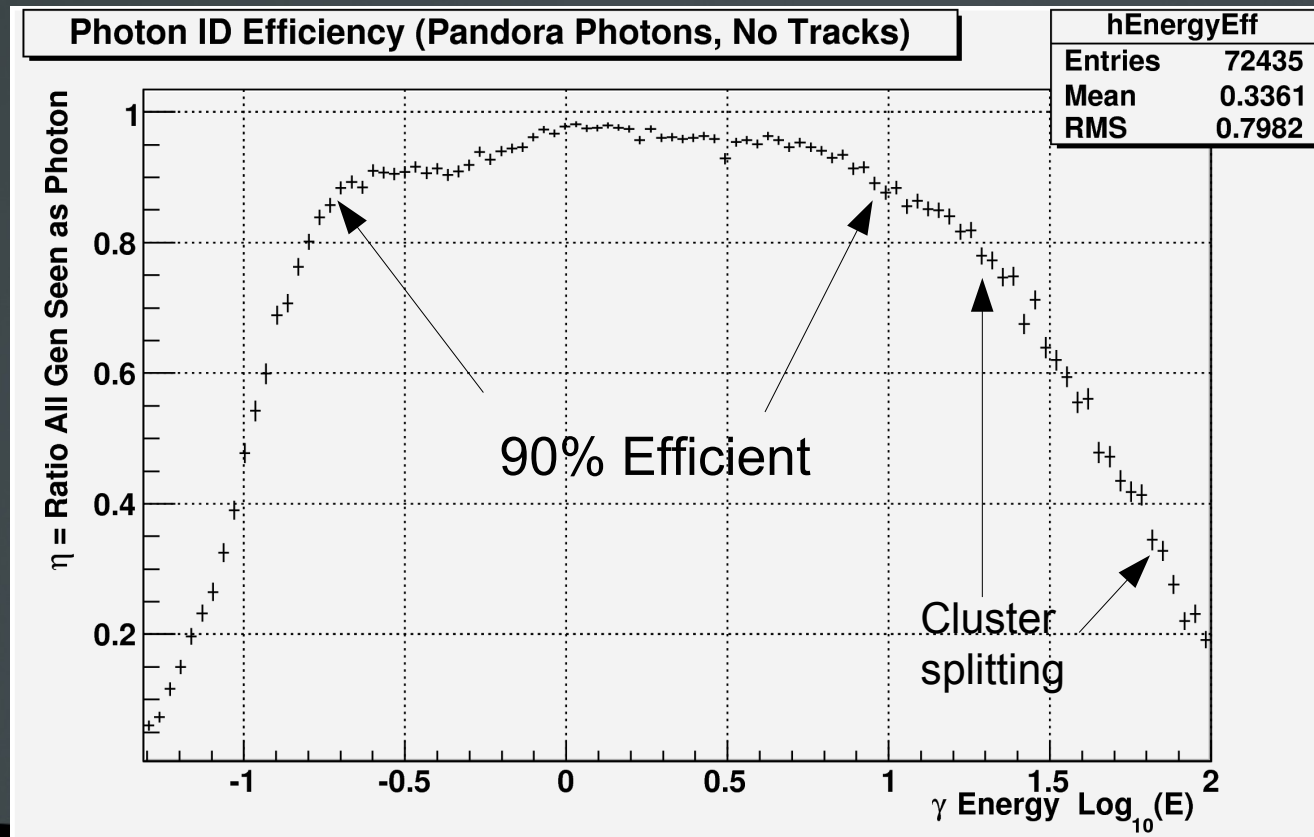

- What happens if we apply this to a more realistic situation? How well can we do?
- Consider 91.2 GeV  $Z^0 \rightarrow q \bar{q}$ ,  $q = u, d, s$
- Extract and simulate the prompt  $\pi^0$ 's and apply fitting procedure using truth information
- Reconstruction uses improved center of gravity position estimate
- Only match photons energy greater than 50 MeV
- Require 95% of energy deposited in barrel
- No tracks in the event

# Fitting Multiple $\pi^0$ 's

- Overall efficiency of correctly detecting photons

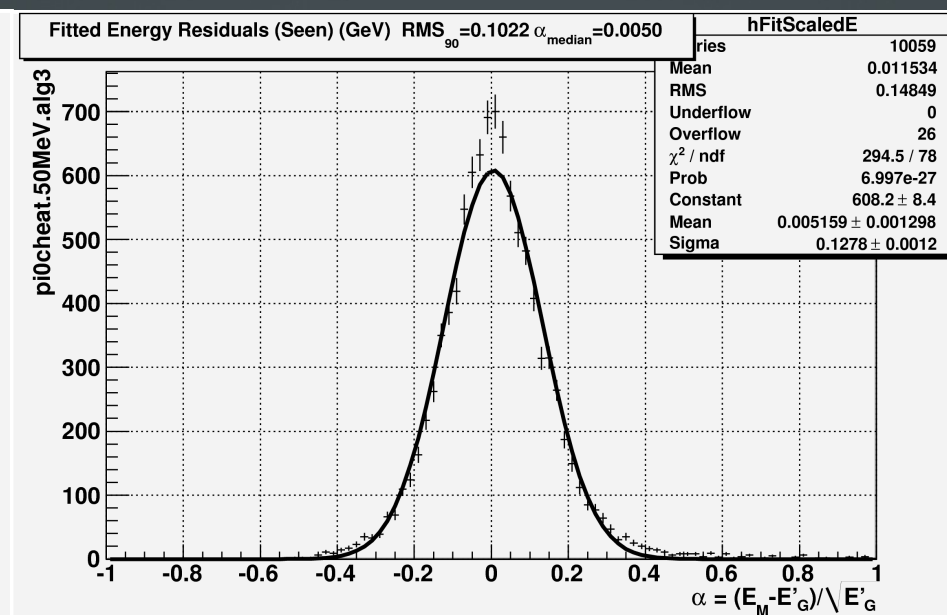

$$\eta = \frac{\text{single PFO identified as photon}}{\text{all photon events with no tracks}}$$

~90% Efficiency  
between  
 $180 \text{ MeV} < E < 10 \text{ GeV}$

# Fitting Multiple $\pi^0$ 's

Results of procedure on 91.2 GeV  $Z^0 \rightarrow q \bar{q}$   
( $\pi^0$  contribution only, 95% energy in barrel,  
50 MeV minimum energy, no tracks)

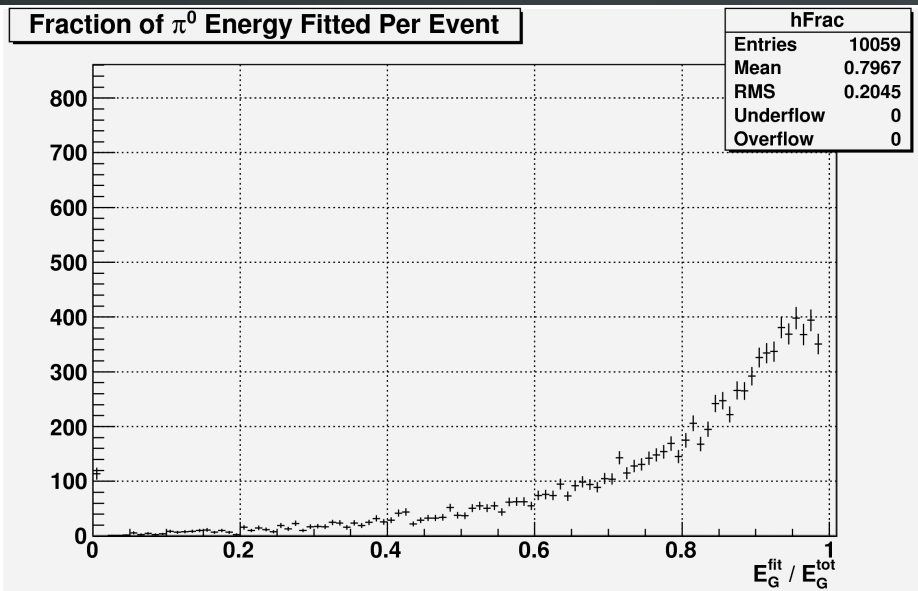

Improvement in  $\alpha$ : .182  $\rightarrow$  .128

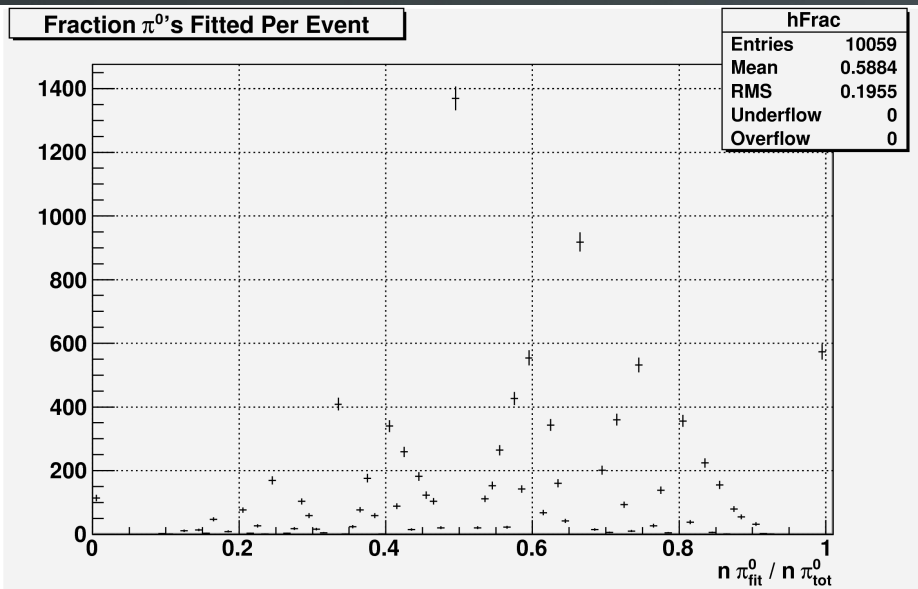

(Using truth information)

# Fitting Multiple $\pi^0$ 's

Fraction of overall energy that is fitted is 79%. Some loss due to 1% probability cut and also undetected photons.

Fraction of  $\pi^0$ 's fitted (59%) suggests fitting favors the higher energy pions, this is likely due to lost low energy photons

# Fitting Multiple $\pi^0$ 's

- Exploration of matching procedures that do **not** use truth information
- The challenge: Enumerate over all potential event solutions and determine the “best”
- Some basic restrictions:

Minimum photon energy 50 MeV

95% of energy deposited in barrel

Accept potential fits with greater than 1% fit probability

- No tracks

# Fitting Multiple $\pi^0$ 's

- Photon Matching Procedure

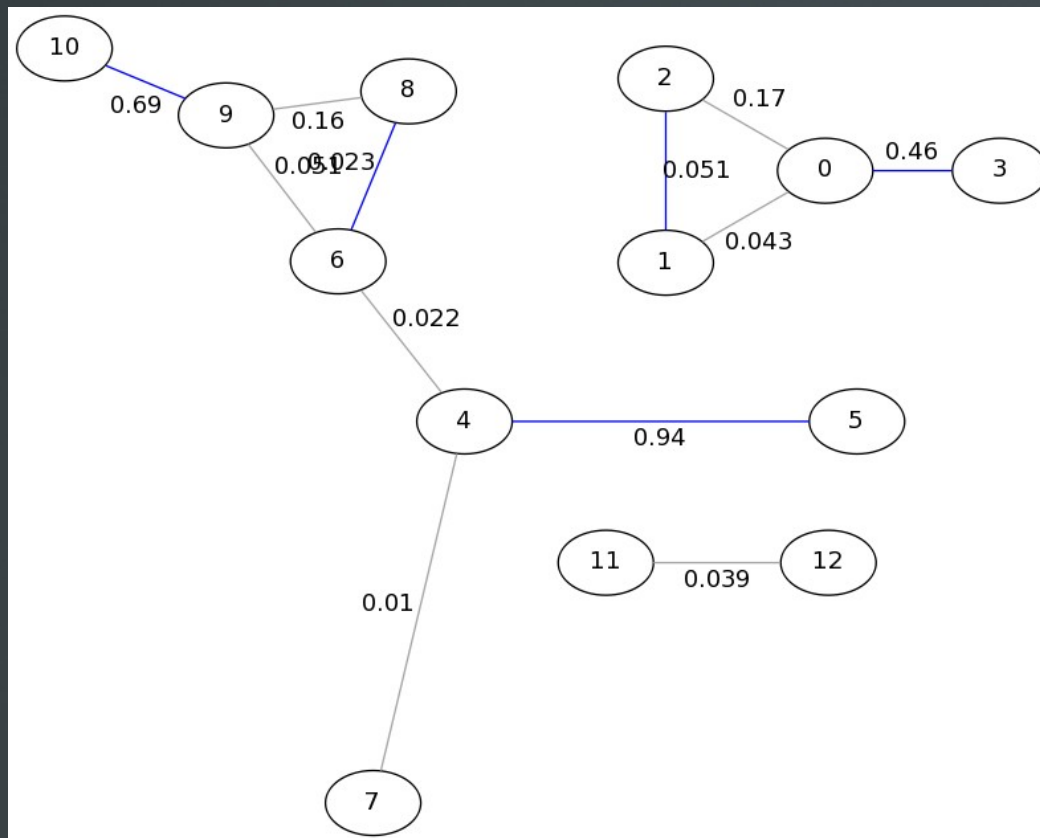

- 1 Perform kinematic fits on all photon pairs
- 2 Remove fits where fit probability is less than 1%
- 3 Generate all potential solutions by combining remaining pairs such that each photon is used at most once
- 4 “Score” each solution and pick the best

# Fitting Multiple $\pi^0$ 's

- Photon Matching Procedure

The collection of all  $>1\%$  pairs can be modeled as a graph with vertices and edges

Vertices are photons

Edges represent fit probability between the photons

(correct edges are blue)

# Fitting Multiple $\pi^0$ 's

- Photon Matching Procedure

Evaluate all solutions

blue = correct

- Final solution uses each photon at most once

# Fitting Multiple $\pi^0$ 's

- Several ways to approach scoring of the solutions:

Evaluated functions involving: fit probability, number of fits, overall  $\chi^2$ .

Best scoring method so far is to consider solutions with maximal fits and the lowest total  $\chi^2$

Example:

Solution a: 6 Fits,  $\chi^2/6 = 5/6$

Solution b: 7 Fits,  $\chi^2/7 = 8.2/7$

Solution c: 7 Fits,  $\chi^2/7 = 14/7$

Best solution is “b”

# Fitting Multiple $\pi^0$ 's

- How does this scale with high multiplicity?  
(i.e. many vertices and edges)
- We use the matching algorithm Blossom V.
  - Finds **perfect match** with minimum cost ( $\chi^2$ )
  - For  $n$  vertices and  $m$  edges, worst case complexity is  $O(n^3m)$  but on average is better than this
  - Most graphs require modification to guarantee perfect match exists

Vladimir Kolmogorov. Blossom V: A new implementation of a minimum cost perfect matching algorithm. *Mathematical Programming Computation (MPC)*, July 2009, 1(1):43-67.

# Fitting Multiple $\pi^0$ 's

- Modification to guarantee perfect match
  - Perfect match: Solution uses each vertex exactly once.
  - Most graphs from detector data do not allow this
  - Modify by duplicating graph and linking each vertex with its duplicate

G. Schäfer. Weighted matchings in general graphs. Master's thesis, Fachbereich Informatik, Universität des Saarlandes, Saarbrücken, Germany, 2000.

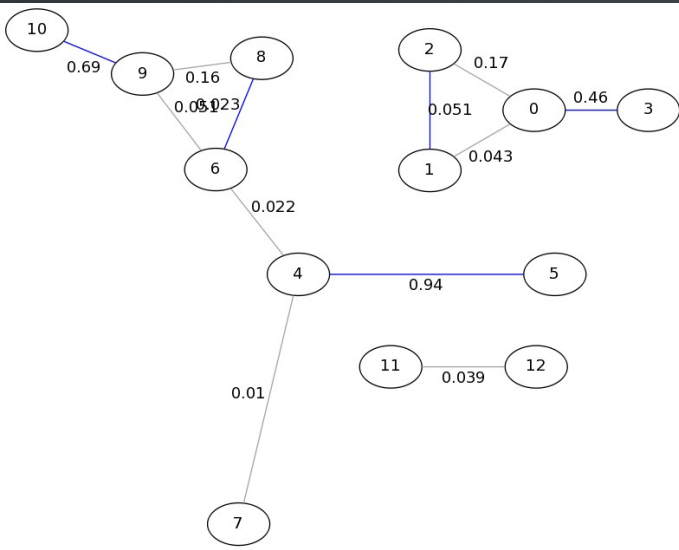

—————>  
This allows  
photons to  
remain  
unmatched if  
necessary  
—————>

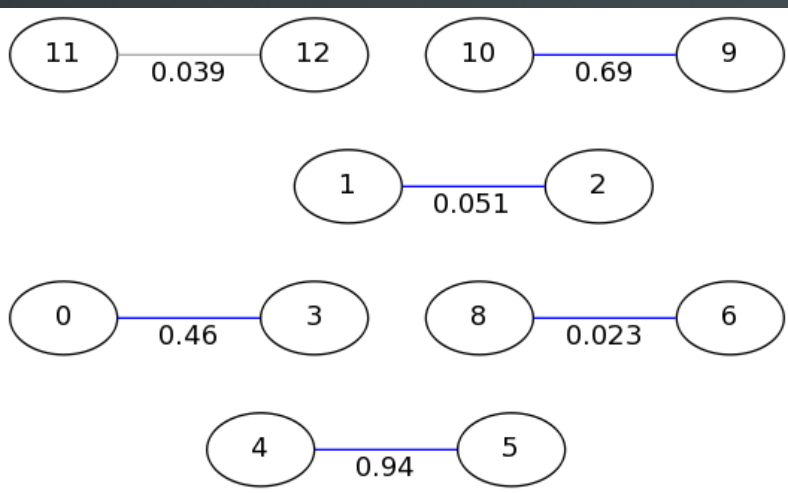

# Fitting Multiple $\pi^0$ 's

- The complete process

Modify graph

Best solution

# Fitting Multiple $\pi^0$ 's

- Fitting 91.2 GeV  $Z^0$  using only  $\pi^0$  photons

Reconstructed

Fitted: Blossom5, Max Fits, Min  $\chi^2$

$\alpha = .182 \rightarrow \alpha = .151$

(much better than ALCPG11 numbers)

(recall best possible  $\alpha = .128$ )

# Fitting Multiple $\pi^0$ 's

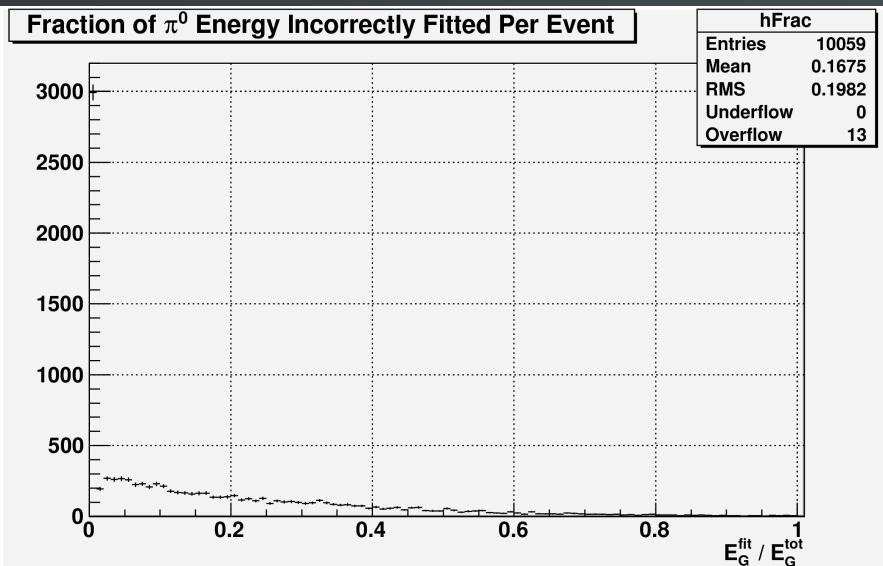

- Overall solution probability is nearly flat, similar to when truth information is used.

# Fitting Multiple $\pi^0$ 's

Fraction of overall energy that is correctly fitted is 67% (compared to 79% when cheating) while 17% is incorrectly fit.

What is the impact of incorrect fits?

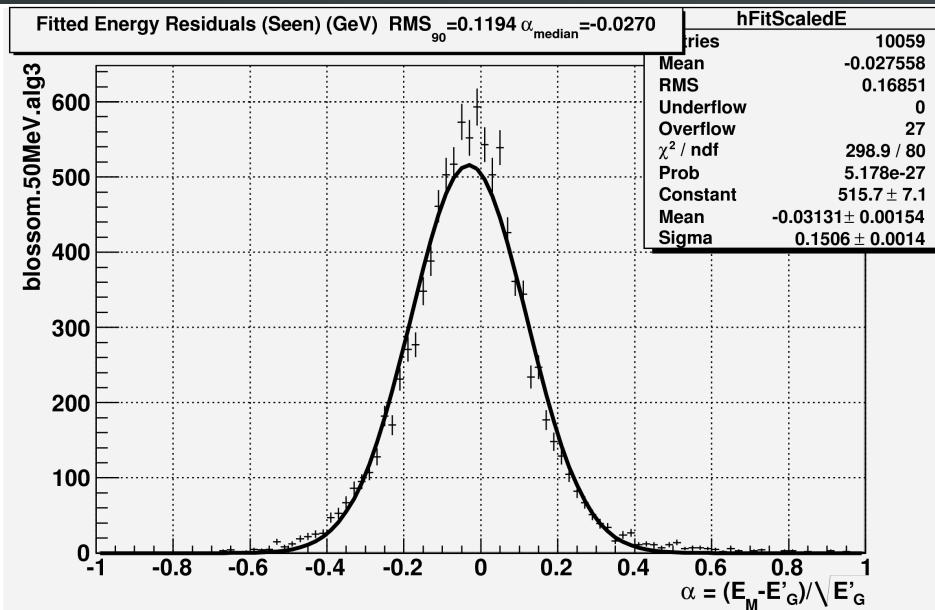

# Fitting Multiple $\pi^0$ 's

- What is the impact of incorrect fits?

Blossom5, Max Fits, Min  $\chi^2$

Blossom5, Max Fits, Min  $\chi^2$ ,  
Remove incorrect fits

Primary impact is some worsening of resolution and a small bias in the energy.

# Fitting Multiple $\pi^0$ 's

- Tuning the Algorithm for 91.2 GeV  $Z^0$ 
  - To minimize fitted sigma, studied range of values for the following and found optimal:
    - Fit Probability Cut = 0.01
    - Single Photon Chi2 = 6.6348 ( $p = 0.01$ )
    - Minimum Photon Energy =  $\sim 50$  MeV  
This is in region where photon detection is not efficient, but benefits still exist by contributing to overall matching solution.

# Summary

- On an individual basis, mass constrained fitting can greatly improve energy resolution of a neutral pion  
17.2% to 8.7% at 4 GeV
- Application to multiple  $\pi^0$ 's from  $Z^0$  decay in ILD\_00 sees significant improvement in energy resolution
  - From 18.2% down to 15.1% (compare to cheating 12.8%) using shower CoG cluster position estimate
- Further Study:
  - Use additional information to inform the matching process
  - Removal of incorrect fits
  - Explore higher energies
  - Cluster splits

# Back up slides

# International Large Detector (ILD)

- Detector concept being studied for the International Linear Collider (electron-positron).

## ECAL

- 20+9 Layers Si-W
- Active layer segmented into 5mm x 5mm “highly granular”
- Typical photon uncertainties

$$\sigma_E = 16\% \sqrt{E}$$

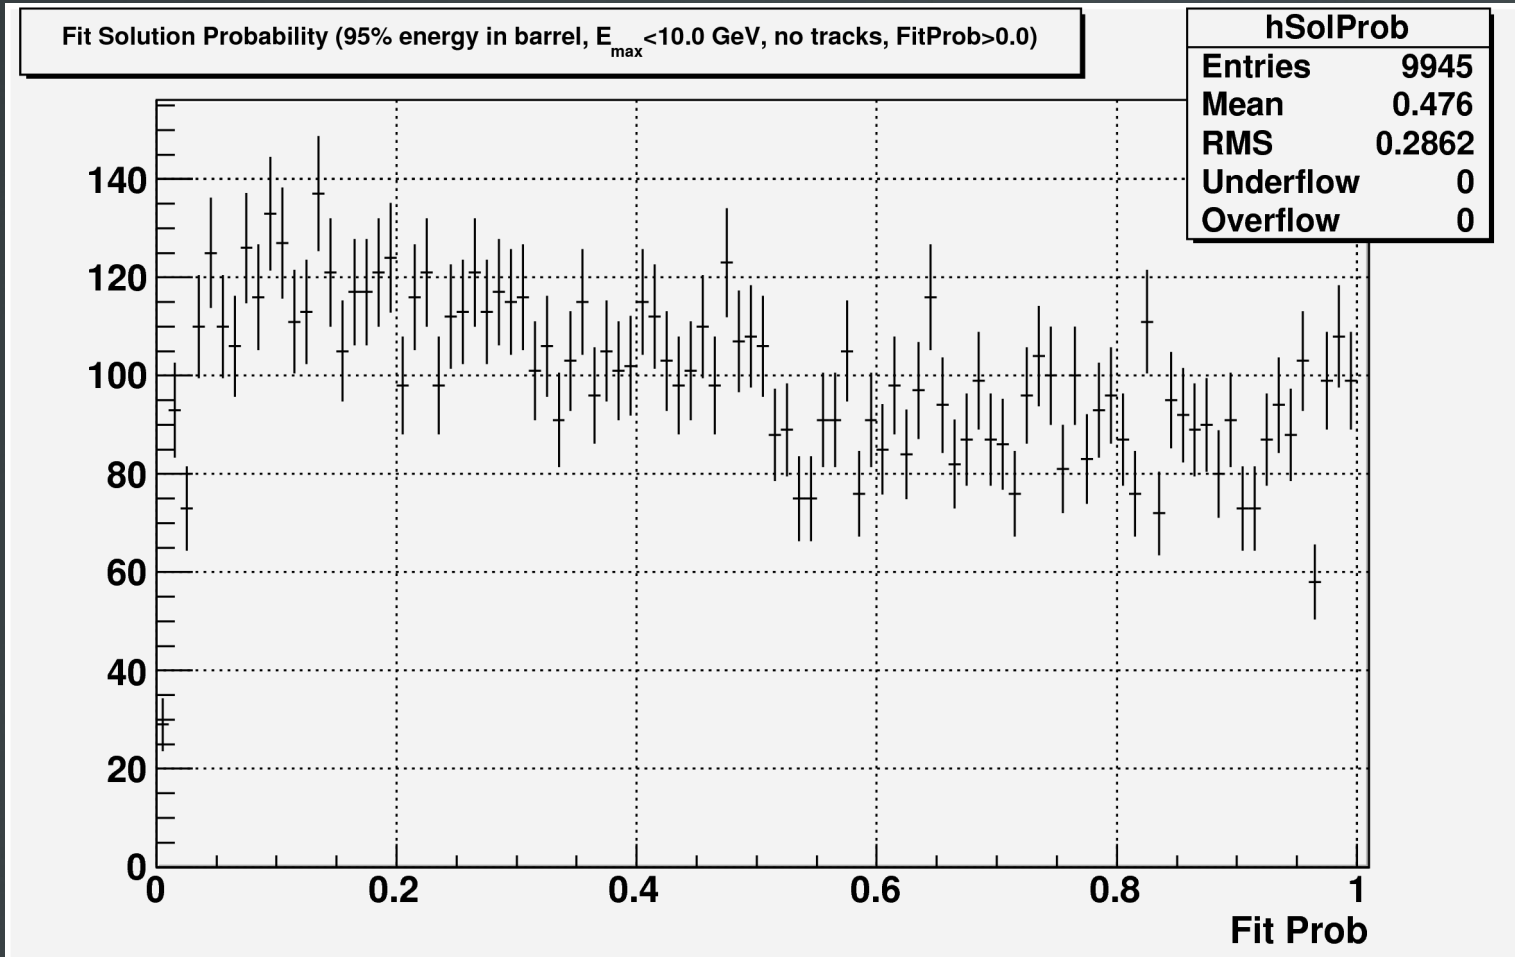

$$\sigma_\phi = 1.2 \text{ mrad @ } 1 \text{ GeV}$$

$\sigma_\theta$  = similar, but  $\theta$  dependence

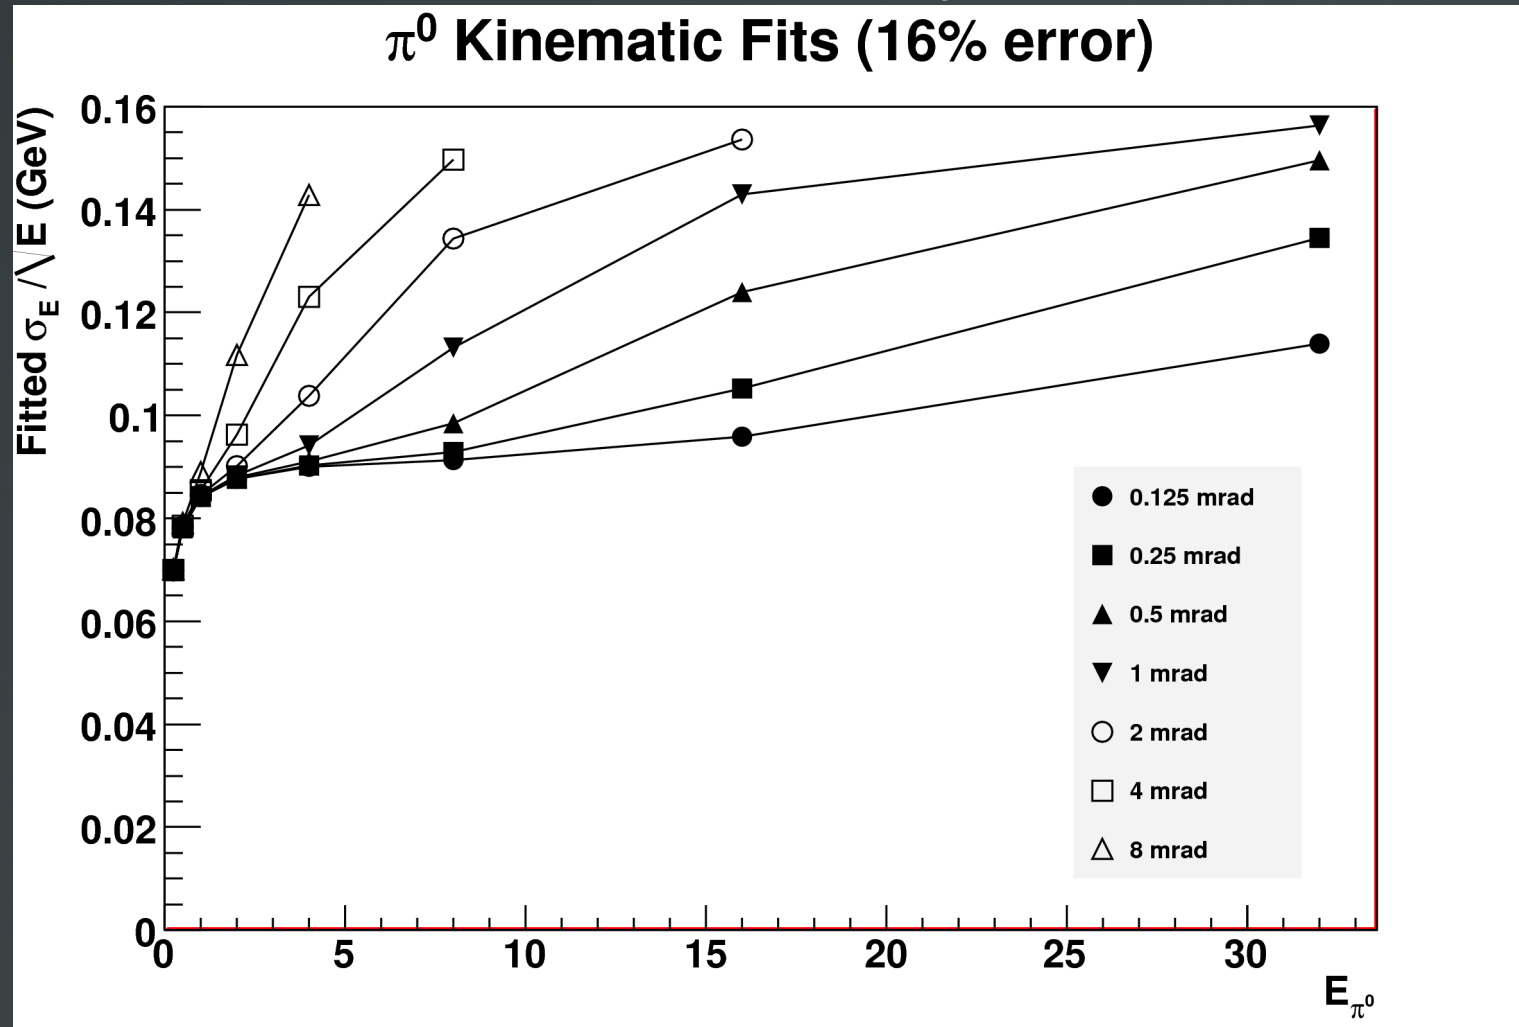

# Fitting Multiple $\pi^0$ 's

Overall solution probability is reasonably flat when using MC truth information

# Fit performance by Energy and Angular Uncertainty

# 4.0 GeV $\pi^0$ Mass Constrained Fits

- Greatest improvement with symmetric decays.

# Software: Simulation and Reconstruction

- Uncertainty Modeling: Accuracy important for kinematic fits.
- Energy Uncertainty as function of Energy  $\frac{\sigma_E}{E} = \frac{.151}{\sqrt{E}} + 0.0095$

# Software: Simulation and Reconstruction

- Uncertainty Modeling: Phi

- “Turns over” or “flattens out” at low energies

# Software: Simulation and Reconstruction

## ■ Uncertainty Modeling: Theta

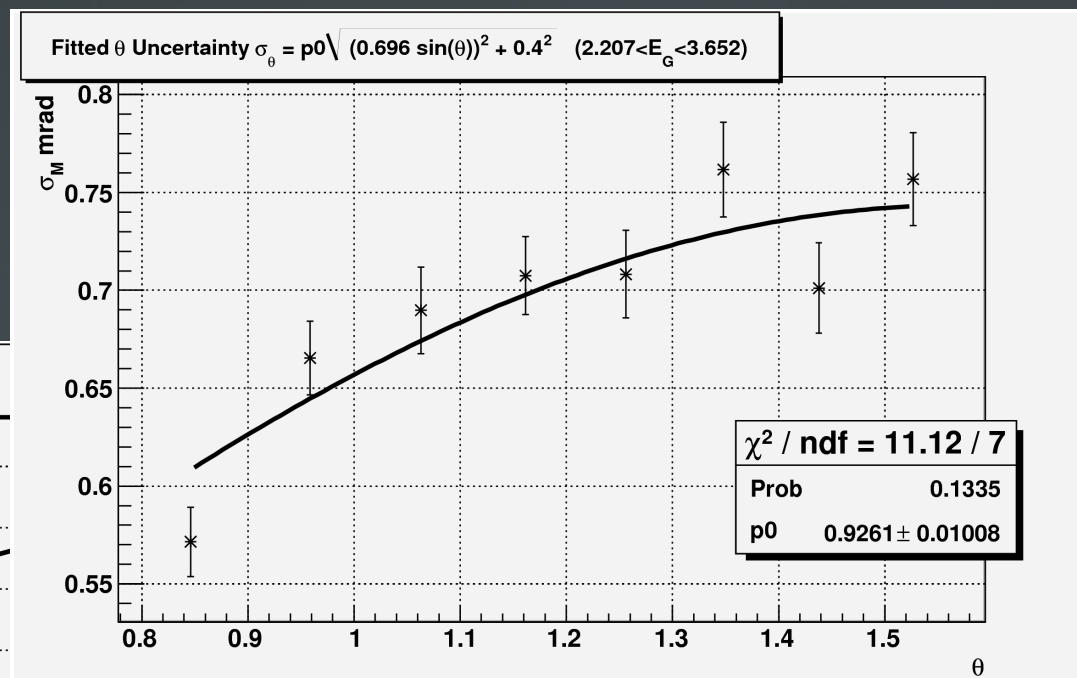

Want smooth function

Hypothesis:  $\sigma_\theta \rightarrow \sigma_\phi$  as  $\theta \rightarrow \pi/2$

$\sigma_\theta \rightarrow 0$  as  $\theta \rightarrow 0$

Try:  $\sigma_\theta^2 = 0.91^2 [(\sigma_\phi^* \sin(\theta))^2 + 0.4^2]$

$$\sigma_\phi^* = \sqrt{\sigma_\phi^2 - 0.4^2}$$

# Fitting Multiple $\pi^0$ 's

Using truth information,  
matching is about 80%  
efficient for 8  $\pi^0$ 's at 4  
GeV

Why is it not 100%?

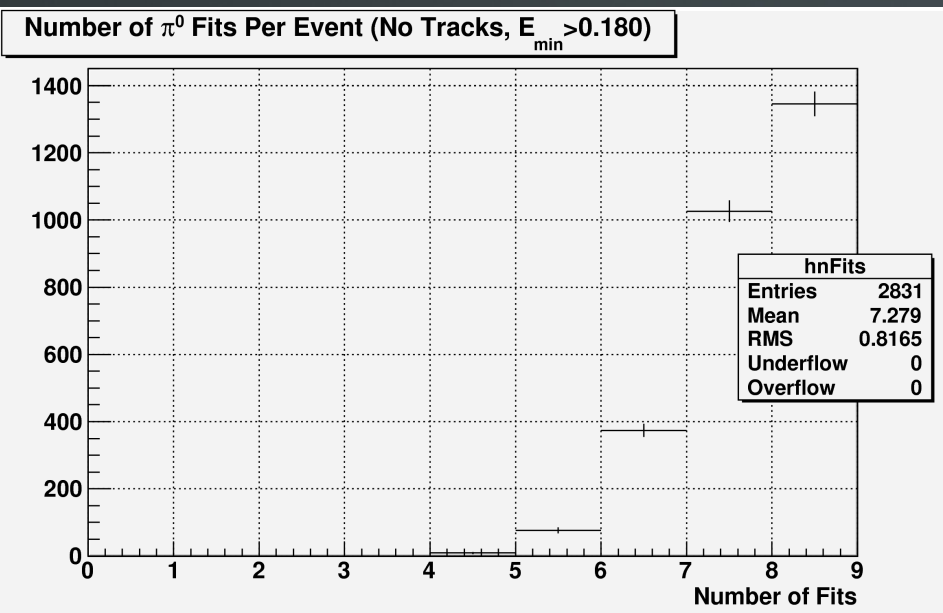

- $e^+e^-$  pair production
- low energy photon cut (180 MeV)
- Base 1% fit probability cut

# Fitting Multiple $\pi^0$ 's

Removing events with tracks increases efficiency to  $\sim 84\%$

← Additionally, removing events with photons below 180 MeV results in  $\sim 91\%$  efficiency

$$\binom{n}{k} p^k (1-p)^{n-k}$$

Consistent with binomial distribution where  $p = .99^8$  suggesting 1% cut responsible for remainder

# Fitting Multiple $\pi^0$ 's

Measured Energy Residuals (8 x 4GeV  $\pi^0$ 's)  $RMS_{90}=0.139$

hRecoScaledE	
Entries	9999
Mean	0.01121
RMS	0.1753
Underflow	0
Overflow	0

At 80% matching efficiency the energy uncertainty (RMS) improves

$$\alpha = 17.5\%$$

to

$$\alpha = 13.5\%$$

Fitted Energy Residuals (8 x 4GeV  $\pi^0$ 's)  $RMS_{90}=0.105$

hFitScaledE	
Entries	9999
Mean	0.004725
RMS	0.1352
Underflow	0
Overflow	0

$$\frac{\alpha}{\sqrt{E}} = \frac{\Delta E}{E}$$

# Fitting Multiple $\pi^0$ 's

- Comparison to truth information (8 x 4 GeV  $\pi^0$ 's)

Max Fits, Min  $\chi^2$

Truth Information

Fitted Energy Residuals (8 x 4GeV  $\pi^0$ 's)  $RMS_{90} = 0.106$

Fitted Energy Residuals (8 x 4GeV  $\pi^0$ 's)  $RMS_{90} = 0.105$

Performance is nearly identical  
(for this situation)

$\alpha = .137$  vs.  $\alpha = .135$

# Fitting Multiple $\pi^0$ 's

- How do these efficiencies vary with multiplicity and energy?

## 4 GeV $\pi^0$ 's

# of $\pi^0$ 's per event	2	4	8	16	32
% $\pi^0$ 's Fit	79	79	80	78	77.7
Unfitted $\alpha$	.179	.176	.175	.180	.175
Fitted $\alpha$	.137	.137	.135	.137	.139

## 8 $\pi^0$ 's per event

Energy (GeV)	4	8	16	32
% $\pi^0$ 's Fit	80	78.3	63.6	46.3
Unfitted $\alpha$	.175	.179	.189	20.8
Fitted $\alpha$	.135	.162	.197	20.8

Angular resolution limits high energy fits

$$\frac{\alpha}{\sqrt{E}} = \frac{\Delta E}{E}$$

# Fitting Multiple $\pi^0$ 's

- How does this method compare to using truth information?

4 GeV  $\pi^0$ 's

# of $\pi^0$ 's	2	4	8	16
% $\pi^0$ 's Fit	79	79.5	79.3	74.7
% Correct	79	79	78.0	72.9
Cheating	79	79	80	78

8  $\pi^0$ 's per event

Energy (GeV)	4	8	16
% $\pi^0$ 's Fit	79.3	79.0	66.3
% Correct	78	77.9	63.6
Cheating	.80	78.3	63.6

Pretty good!
