

# LHC and ILC implications of a 125 GeV Higgs boson in supersymmetry

Oscar Stål

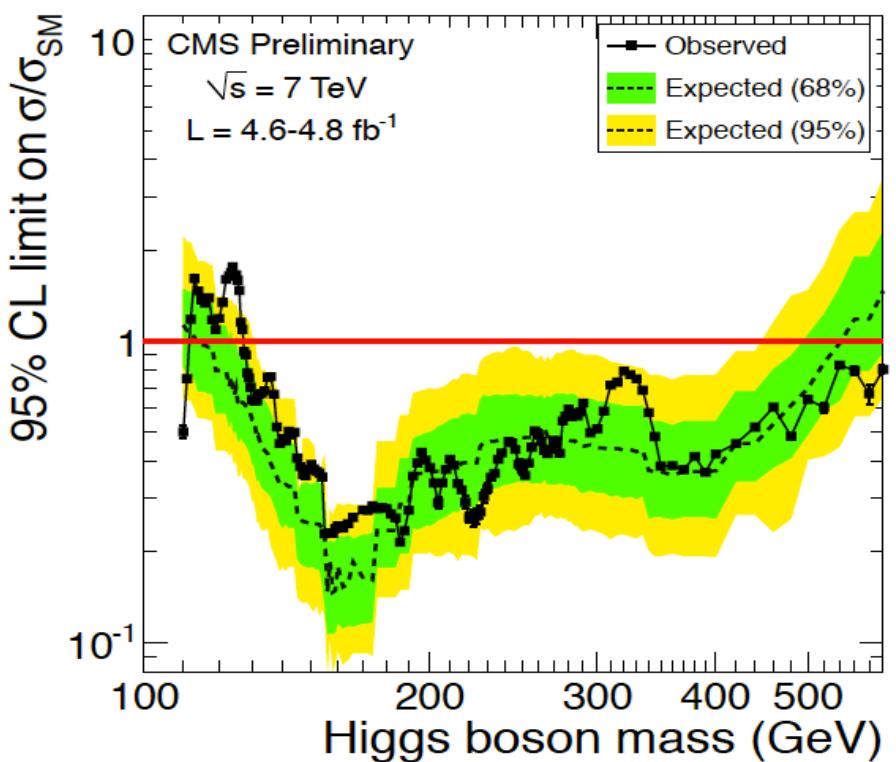

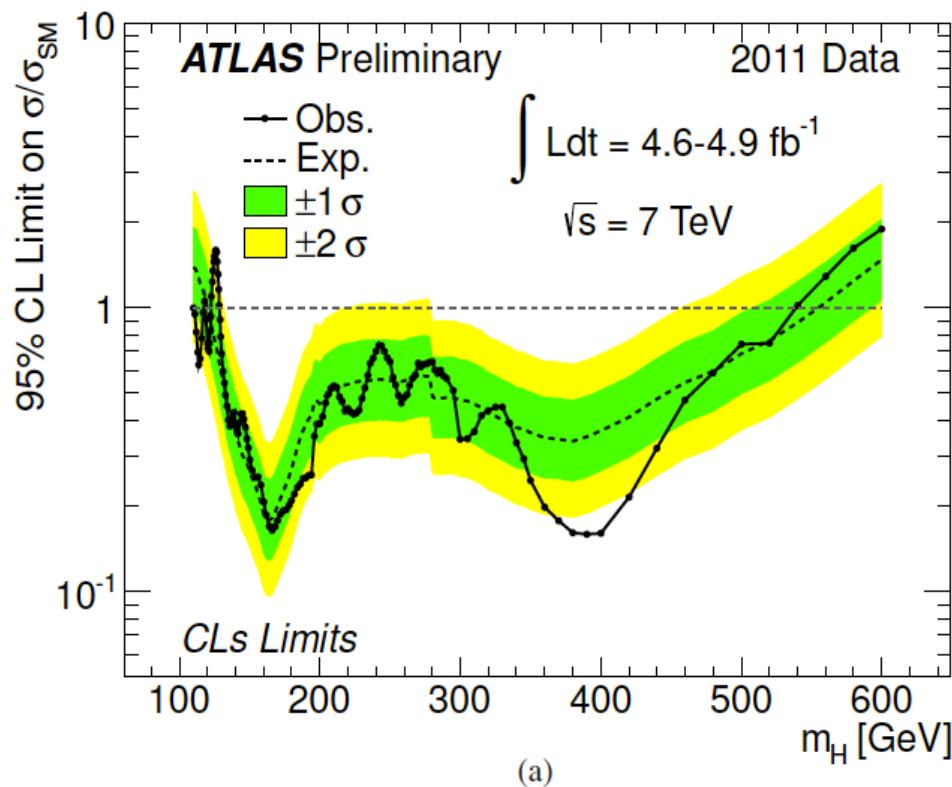

KILC12

Daegu, Korea  
23-27 April 2012

# LHC Higgs Search Results

- Updated SM Higgs search results from ATLAS and CMS at Moriond using full 2011 dataset (close to  $5 \text{ fb}^{-1}$ )
- SM-like Higgs excluded for  $M_H > 130 \text{ GeV}$  -> Good news for SUSY (heavier non-SM Higgses not excluded – model-dependent bounds)

# MSSM Higgs Sector

- Minimal SUSY with two complex Higgs Doublets:  $H_u, H_d$   
-> 8 degrees of freedom, 5 physical Higgs bosons
- CP conservation:  $h, H^-$  (CP-even),  $A$  (CP-odd), and  $H^\pm$   
 $m_H > m_h$
- At tree-level, the Higgs sector is determined by two parameters

$$M_A, \tan \beta = \frac{v_u}{v_d}$$

- Other Higgs masses are *predictions*:

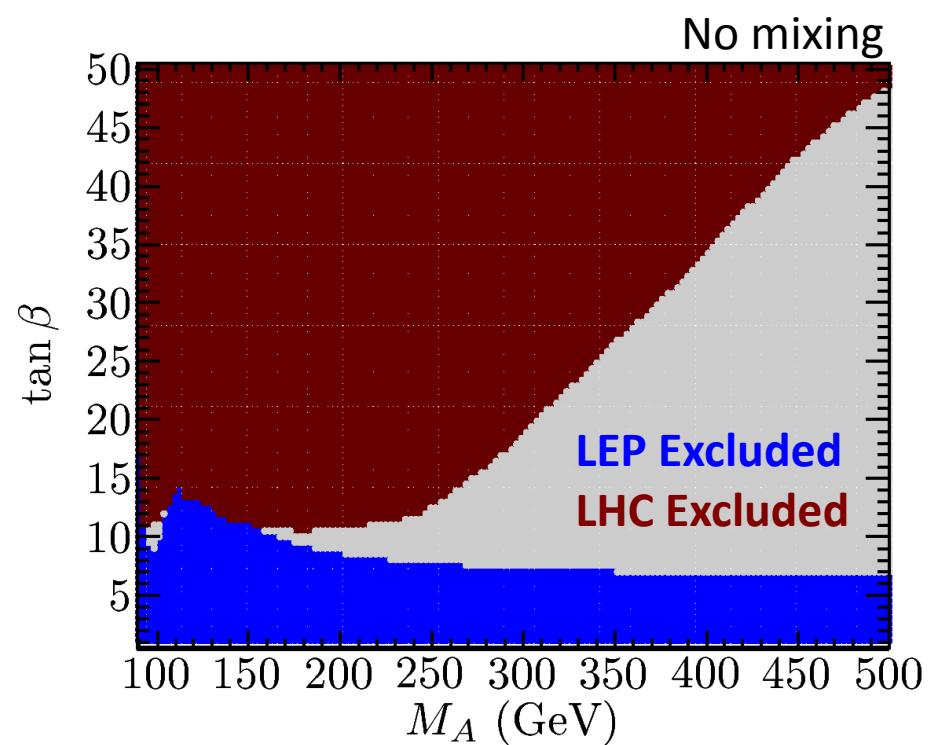

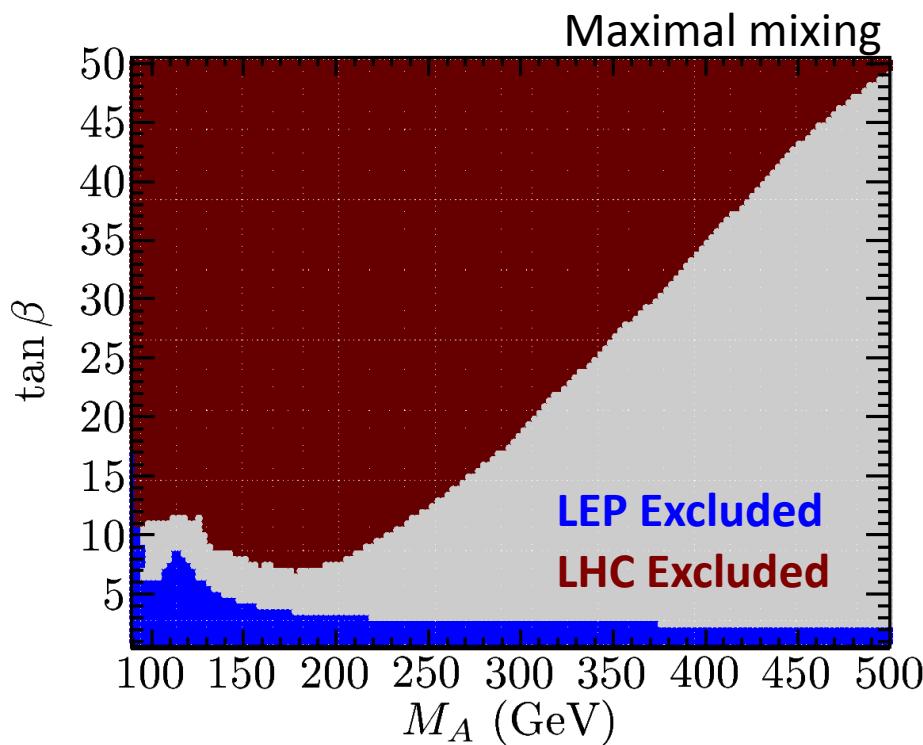

$$M_h^2 = M_{h,\text{tree}}^2(M_A, \tan \beta) + \Delta M_h^2(M_{\text{SUSY}}, A_i, M_i, \dots)$$

$$M_{h,\text{tree}}^2 \leq M_Z^2 \cos^2 2\beta \quad M_h \lesssim 135 \text{ GeV}$$

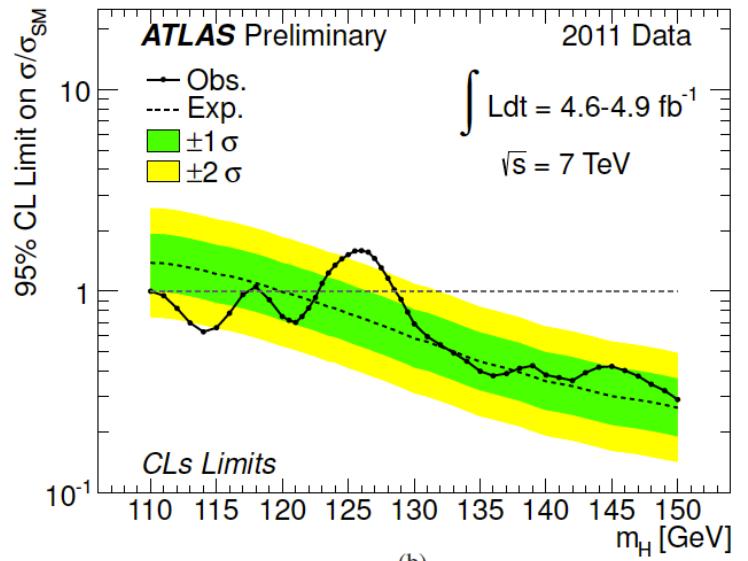

# MSSM Exclusion limits

- In addition to the results for a light SM-like  $h$ , include dedicated searches for heavy SUSY Higgs, e.g.  $H/A \rightarrow \tau\tau$   
 $t \rightarrow bH^+ \rightarrow b\tau^+\nu_\tau$
- Limits at 95% CL (no theory uncertainties on Higgs masses)

HiggsBounds: <http://www.ippp.dur.ac.uk/HiggsBounds>

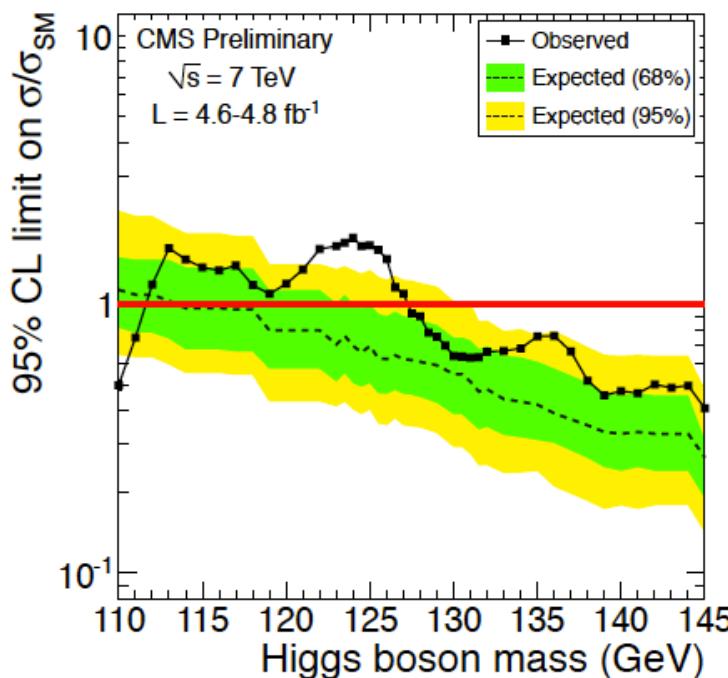

# First hint of a Higgs signal?

ATLAS

Largest excess seen at  $M_H = 126 \text{ GeV}$   
Significance:  $2.5 \sigma$  local ( $2.8 \sigma$  expected)  
 $< 2 \sigma$  including LEE

CMS

Largest excess seen at  $M_H = 125 \text{ GeV}$   
Significance:  $2.8 \sigma$  local, ( $2.8 \sigma$  expected)  
 $2.1 \sigma$  including LEE

+ Interesting Tevatron results

# First hint of a Higgs signal?

-> No time for a review. Not even of the MSSM results.

# MSSM interpretation of $M_h = 125$ GeV

S. Heinemeyer, OS, G. Weiglein, *Phys. Lett.* B710 (2012) 201, [1112.3026]

- We *assume* an MSSM Higgs boson signal is present in LHC data

Experimental result:  $M_h = 125 \pm 1$  GeV

- Higgs spectrum up to 2-loop order calculated with **FeynHiggs**.  
2 GeV theory uncertainty on  $M_h$  (e.g. from missing higher orders)  
added linearly:

$$122 \text{ GeV} < M_h < 128 \text{ GeV}$$

- SM top mass ( $1\sigma$  interval) taken as parametric uncertainty

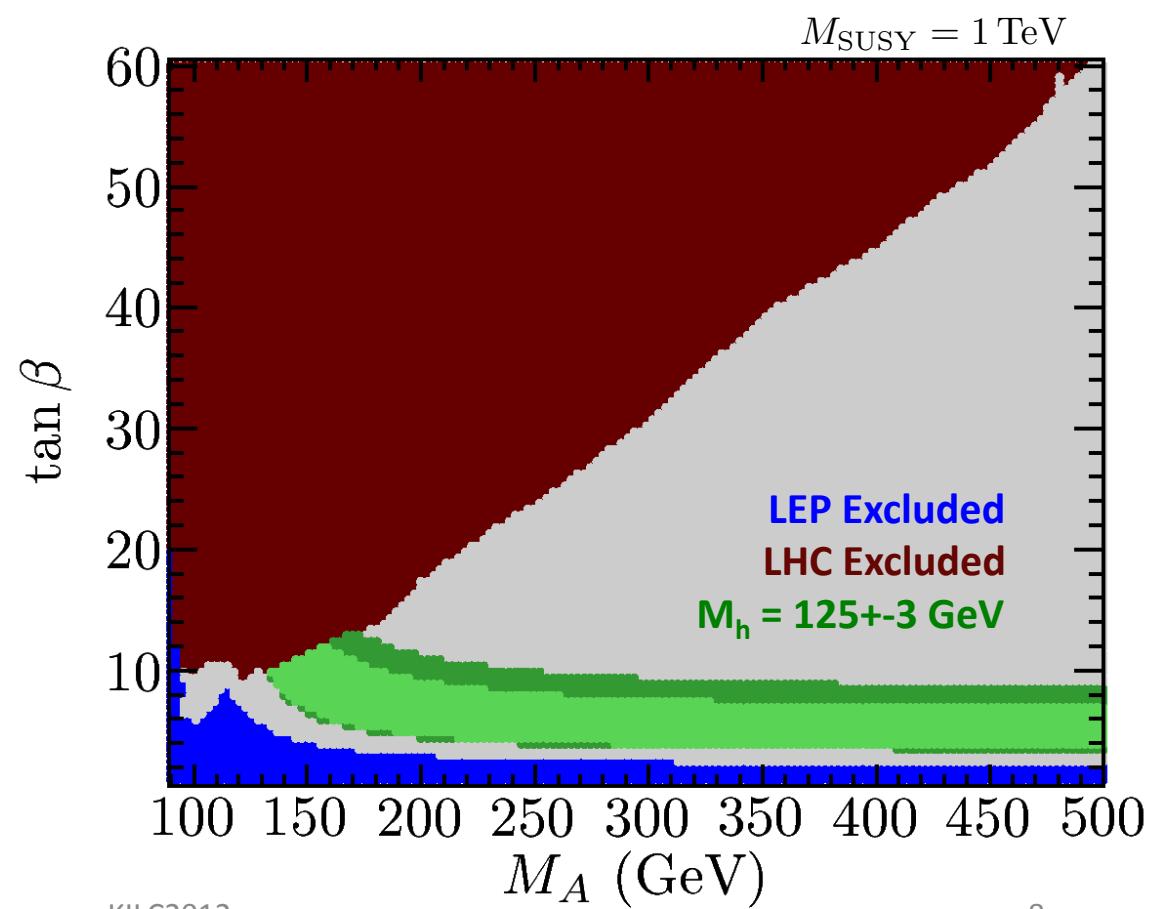

$$m_t = 173.2 \pm 0.9 \text{ GeV}$$

# Lower limits on MSSM tree-level parameters

- $M_h$  is increasing function of tree-level parameters
- For a given SUSY mass scale  $M_{\text{SUSY}}$ , maximize the contributions to  $M_h$  from radiative corrections  $\rightarrow$  maximal stop mixing

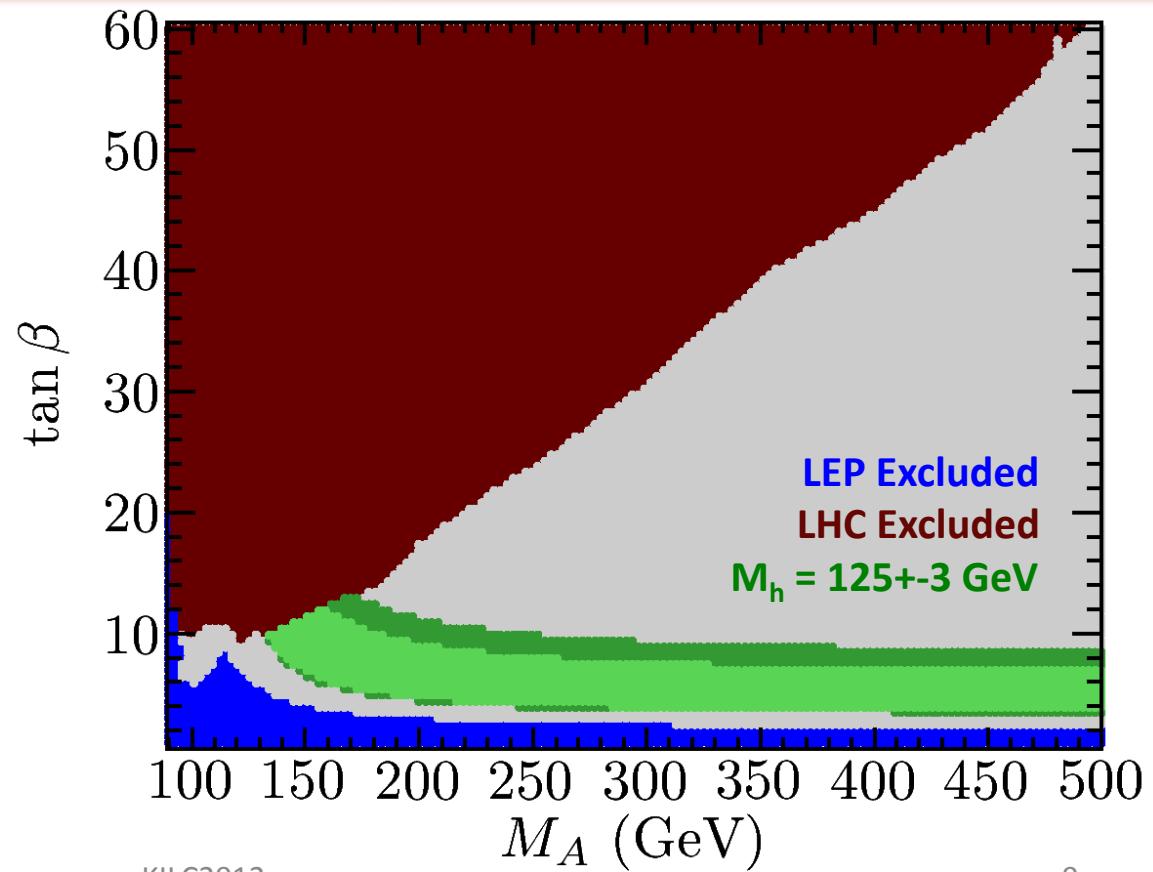

$$X_t = A_t - \mu \cot \beta = 2M_{\text{SUSY}}$$

- Scenario-independent  
*lower* bounds on  $M_A$ ,  $\tan \beta$

# Lower limits on MSSM tree-level parameters

$M_{\text{SUSY}}$ (GeV)	Limits without $M_h \sim 125$ GeV			Limits with $M_h \sim 125$ GeV		
	$\tan \beta$	$M_A$ (GeV)	$M_{H^\pm}$ (GeV)	$\tan \beta$	$M_A$ (GeV)	$M_{H^\pm}$ (GeV)
500	2.7	95	123	4.5	140	161
1000	2.2	95	123	3.2	133	155
2000	2.0	95	123	2.9	130	152

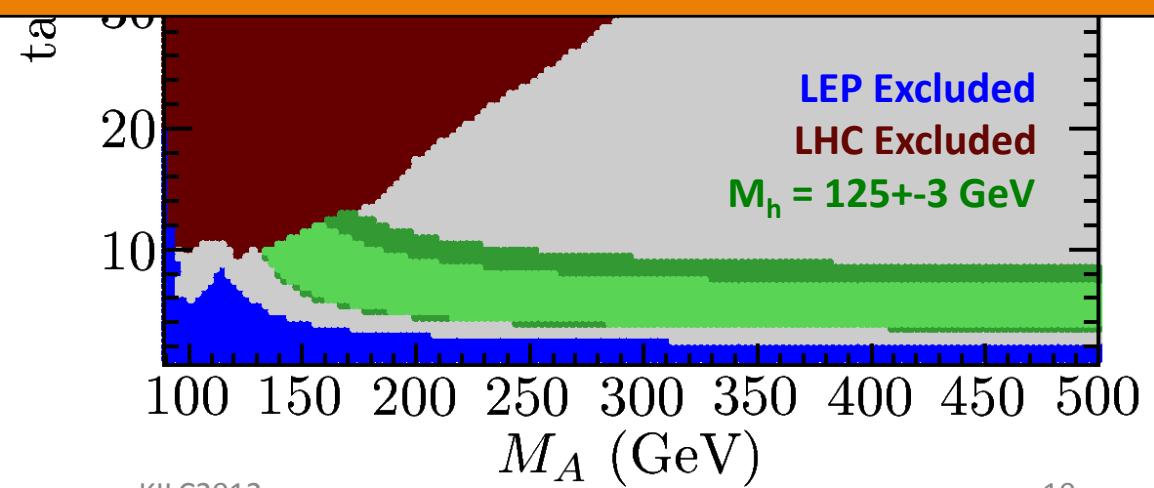

# Lower limits on MSSM tree-level parameters

$M_{\text{SUSY}}$ (GeV)	Limits without $M_h \sim 125$ GeV			Limits with $M_h \sim 125$ GeV		
	$\tan \beta$	$M_A$ (GeV)	$M_{H^\pm}$ (GeV)	$\tan \beta$	$M_A$ (GeV)	$M_{H^\pm}$ (GeV)
500	2.7	95	123	4.5	140	161
1000	2.2	95	123	3.2	133	155
2000	2.0	95	123	2.9	130	152

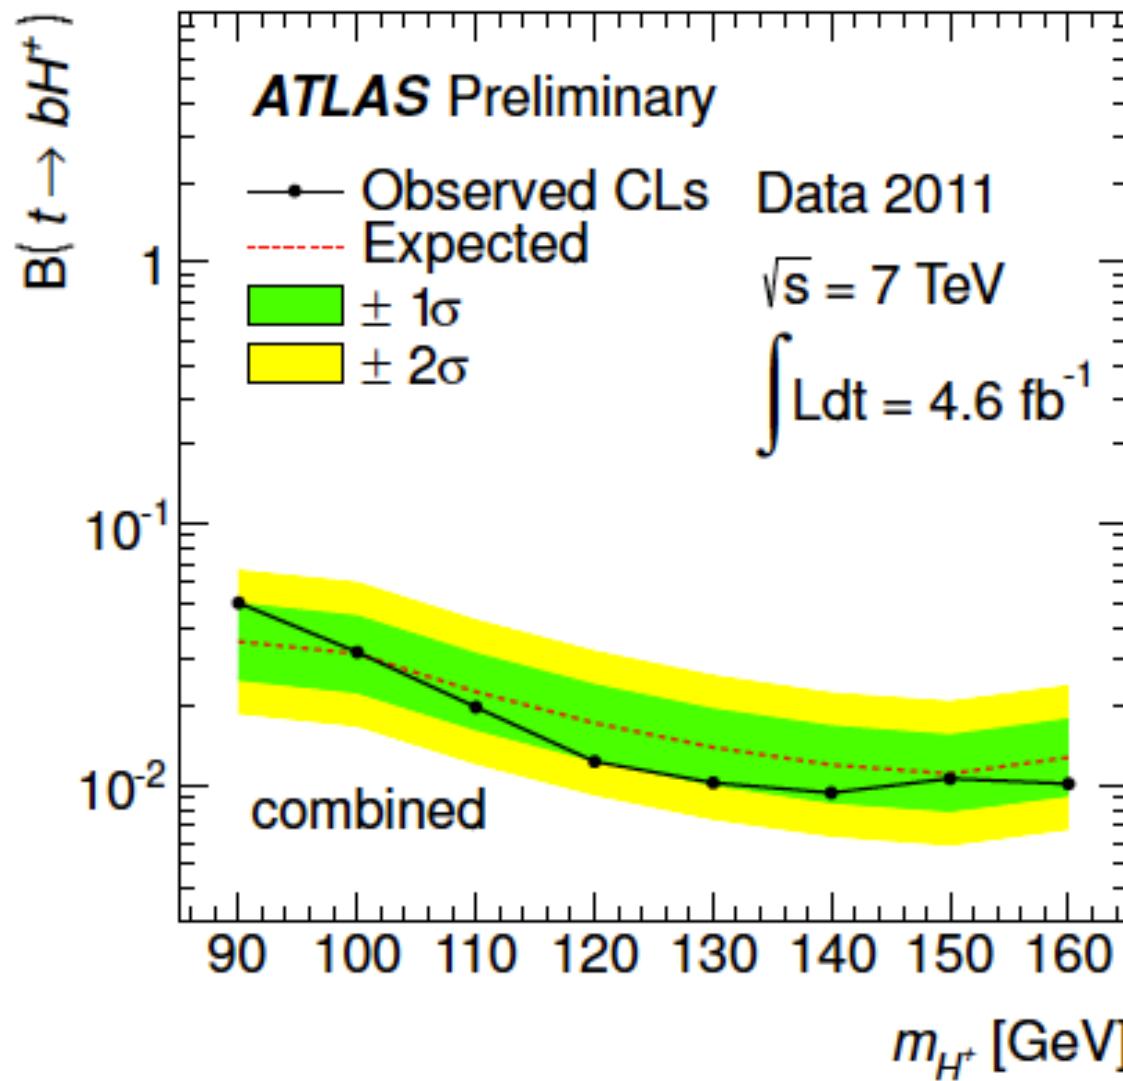

These are scenario-independent *lower bounds from  $M_h$  only*.  
Most MSSM realizations will have *stronger* limits on  $M_A$ ,  $\tan \beta$  !

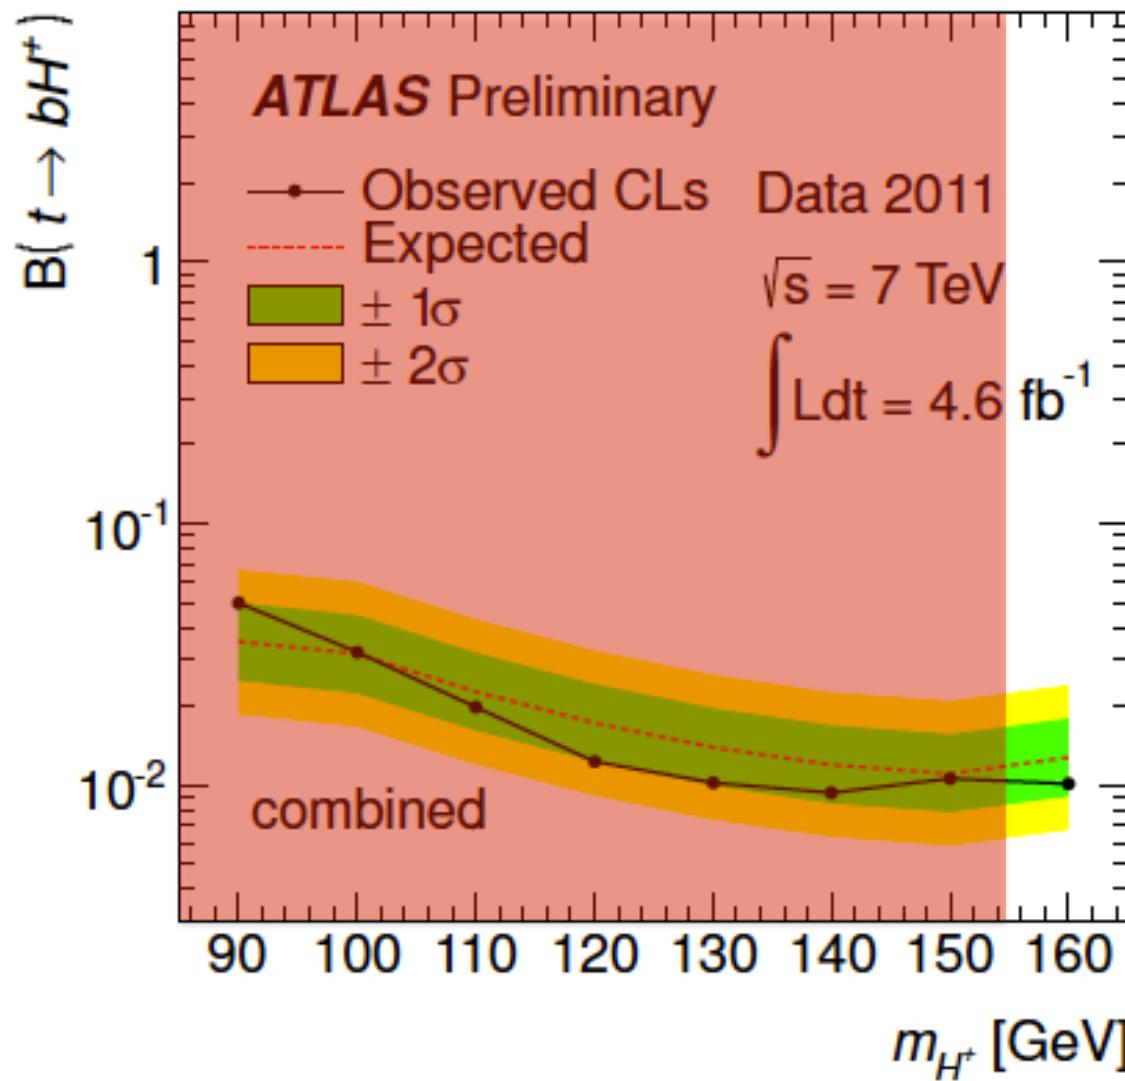

# No room for a light charged Higgs boson

ATLAS-CONF-2012-011

# No room for a light charged Higgs boson

ATLAS-CONF-2012-011

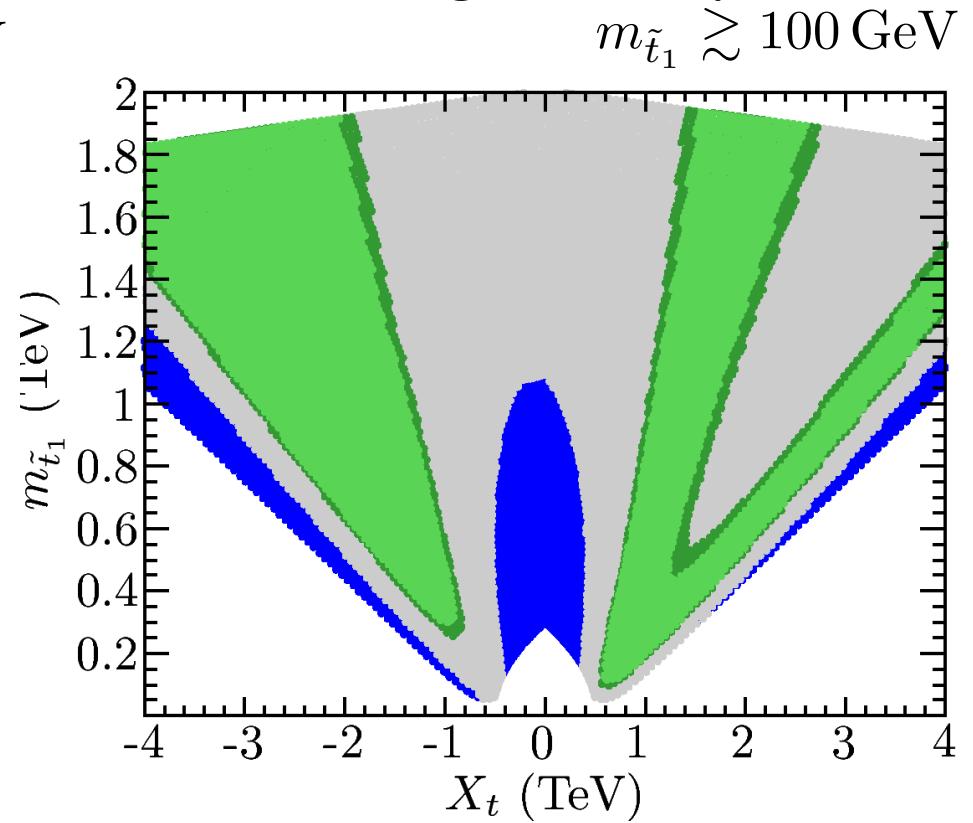

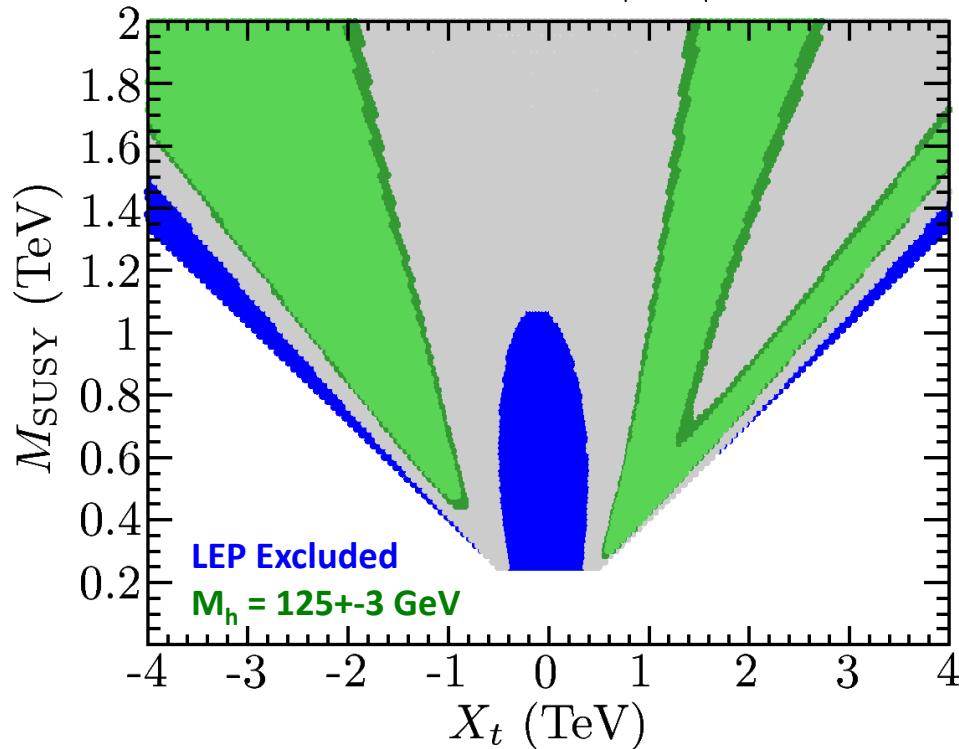

# Constraints on stop sector parameters

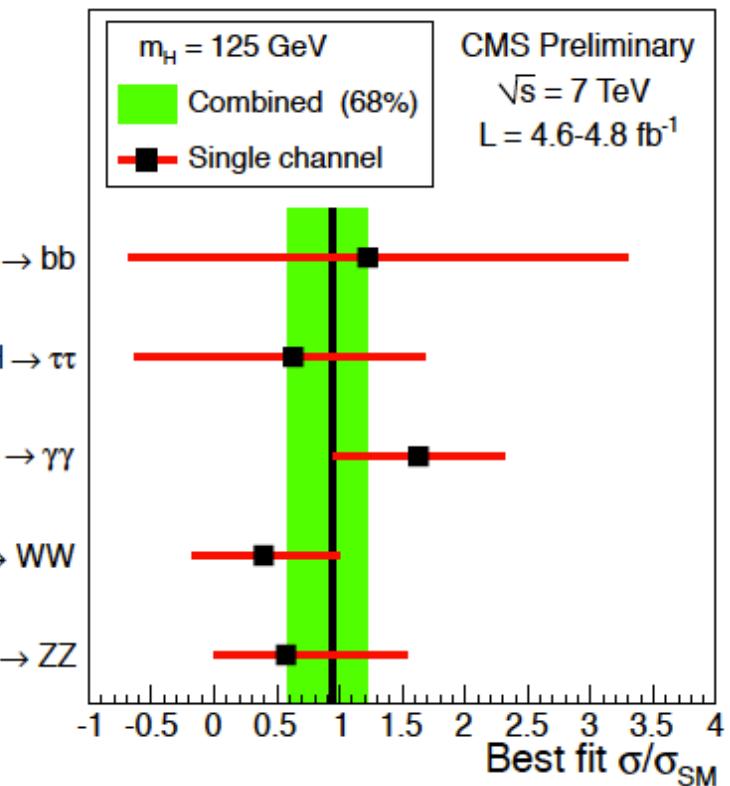

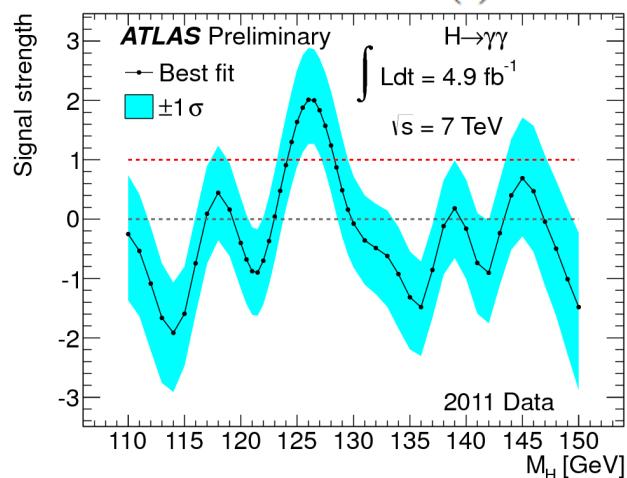

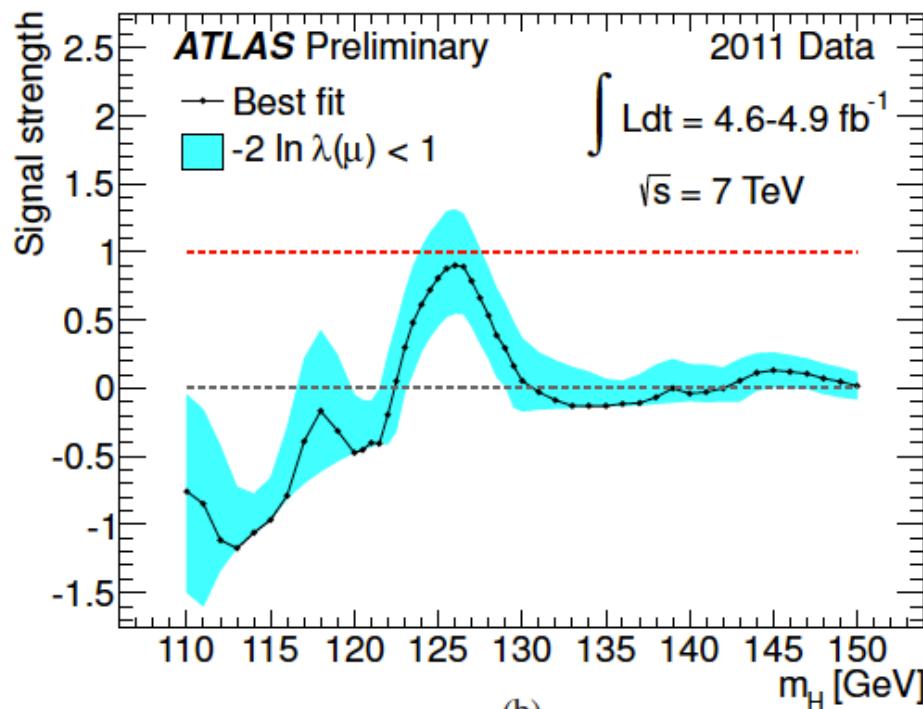

- We can also ask for a lower limit on the amount of radiative corrections by maximizing  $M_{h,\text{tree}} \rightarrow M_Z$  (decoupling limit)

- High SUSY mass scale and/or large stop mixing required  
Can also be interpreted as a lower limit on the lightest stop mass

$$M_{\text{SUSY}} > 300 \text{ GeV}, |X_t| > 600 \text{ GeV}$$

# Including rate information

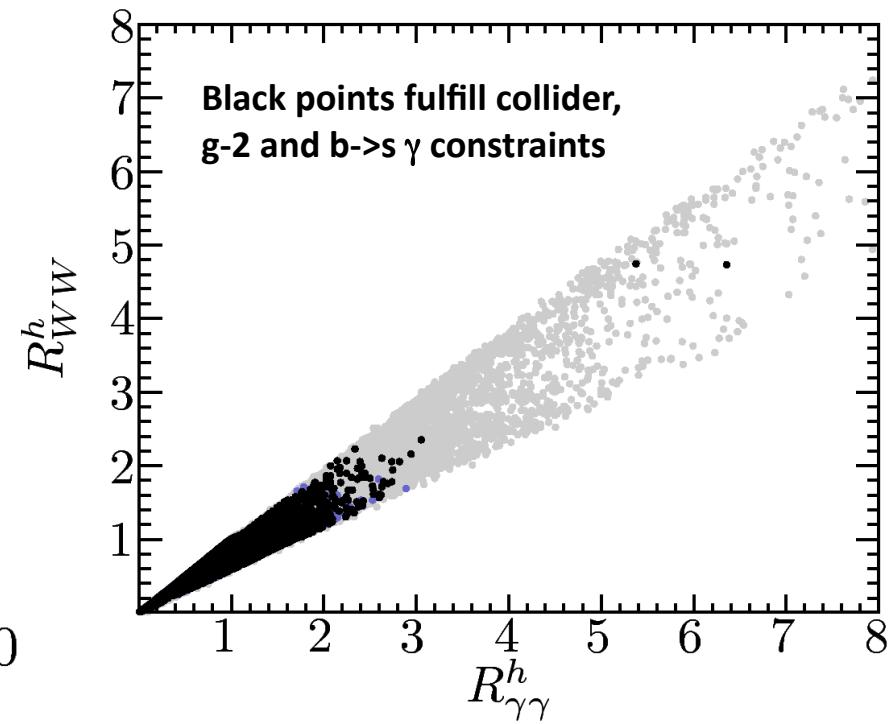

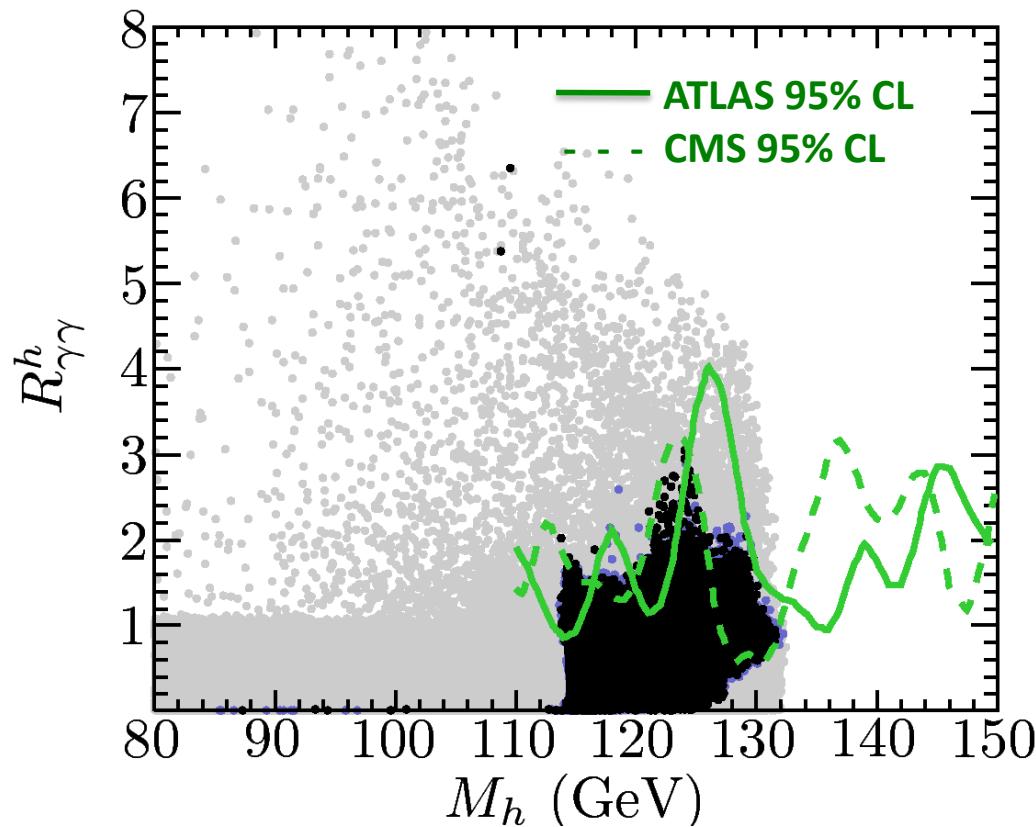

- Best fit signal strength is compatible with SM, with possible room for an enhanced  $\gamma\gamma$

$$R_{\gamma\gamma}^{h_i} = \frac{\sigma(pp \rightarrow h_i) \times \text{BR}(h_i \rightarrow \gamma\gamma)}{\sigma(pp \rightarrow h_i)_{\text{SM}} \times \text{BR}(h_i \rightarrow \gamma\gamma)_{\text{SM}}} \gtrsim 1$$

# MSSM Higgs scenarios with enhanced $\gamma\gamma$ rates

R. Benbrik, S. Heinemeyer, M. Gomez, OS, G. Weiglein, L. Zeune, in preparation

- “Easy” solution: Decoupling limit  $\rightarrow$  SM-like lightest Higgs
- Here: scan over broad range of (low-energy) MSSM parameters to find possible enhancements

# MSSM enhancement of the two photon mode

- Two mechanisms can enhance the MSSM  $h \rightarrow \gamma\gamma$  branching ratio

Contribution from light staus  
can give  $\sim 40\%$  enhancement

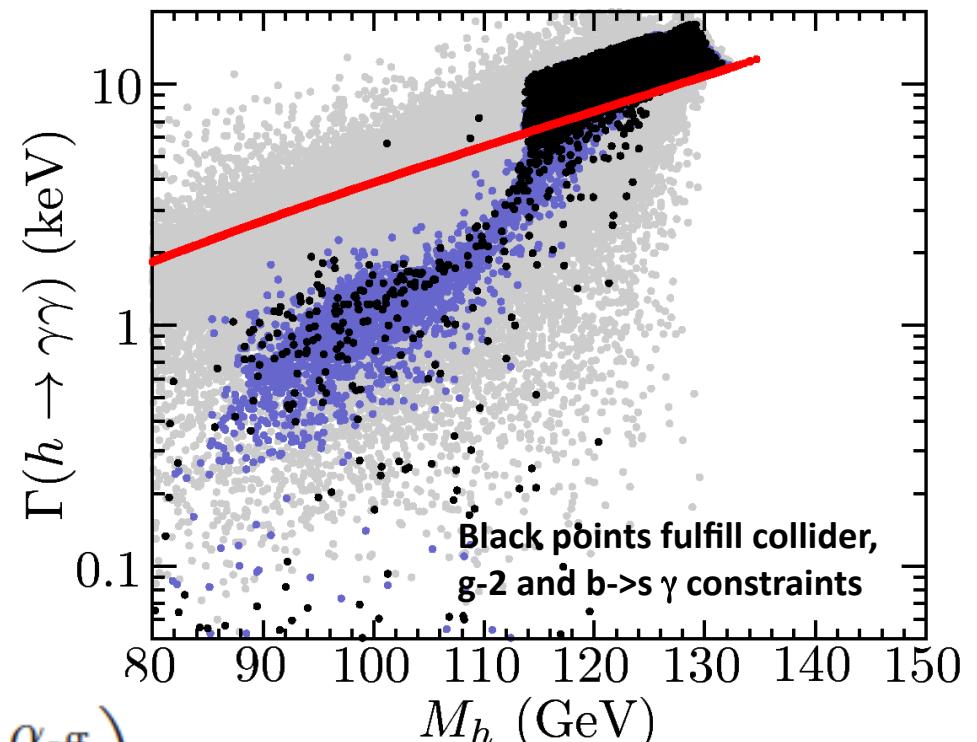

Carena, Gori, Shah, Wagner, [1112.3336]

-> Implies lightest stau mass  
close to current (PDG) bound

- Reduction of  $hbb$  coupling by  
Higgs mixing (small  $\alpha_{\text{eff}}$ )

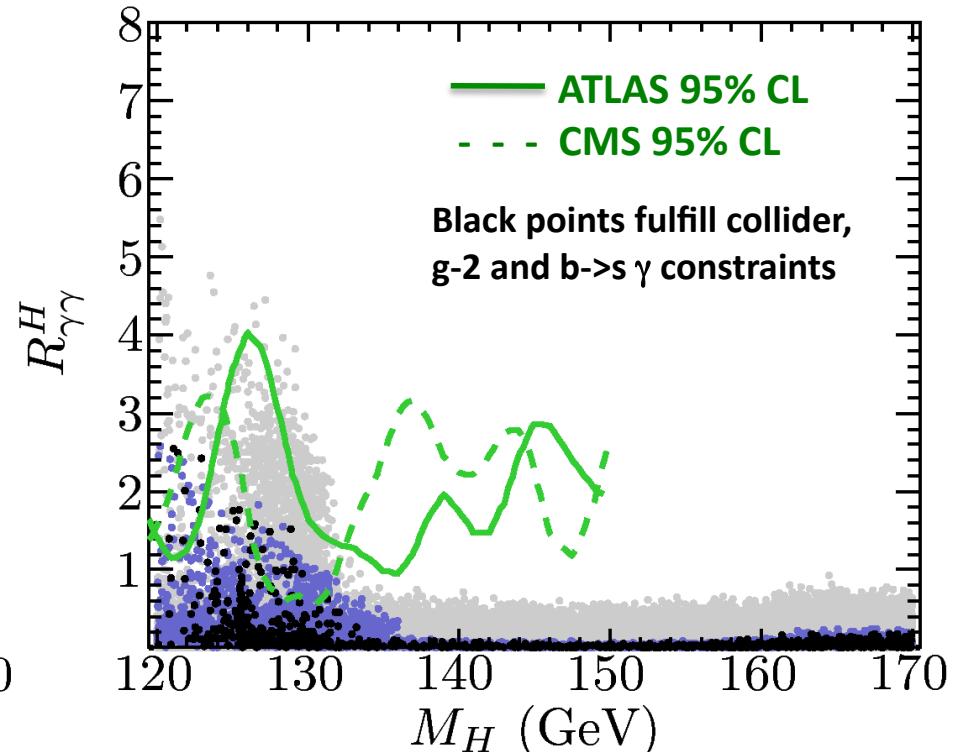

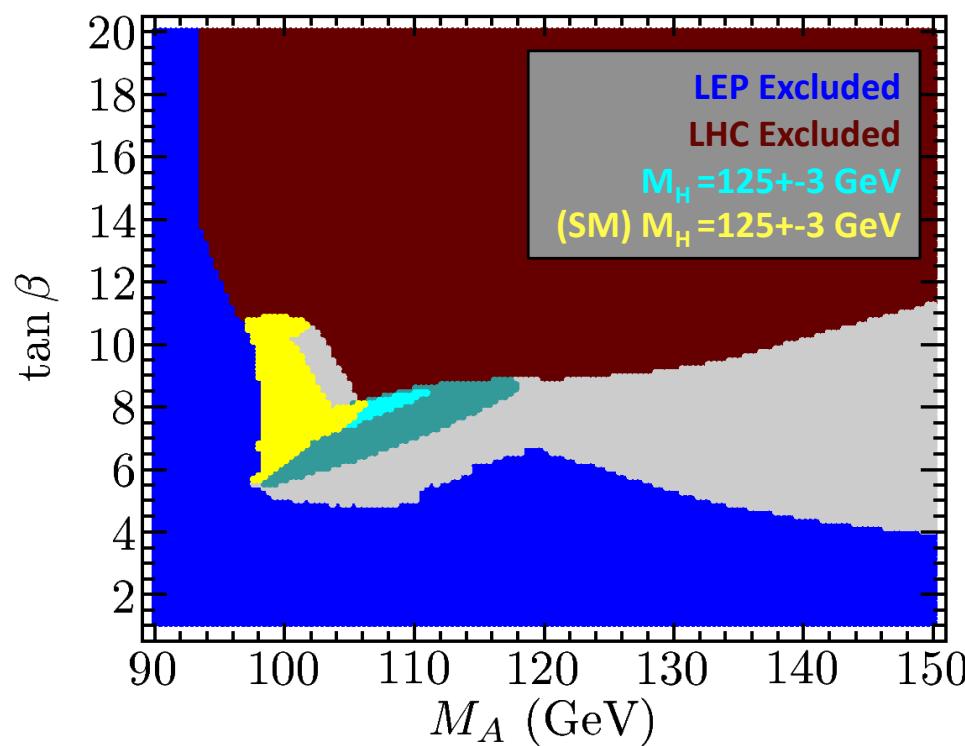

$$\frac{g_{h\bar{b}}}{g_{H_{\text{SM}}\bar{b}}} = \frac{1}{1 + \Delta_b} \left( -\frac{\sin \alpha_{\text{eff}}}{\cos \beta} + \Delta_b \frac{\cos \alpha_{\text{eff}}}{\sin \beta} \right)$$

-> Minimizing  $\alpha_{\text{eff}}$  requires large  $\mu$  and stop mixing, reduces  
 $h \rightarrow bb$  and  $h \rightarrow \tau\tau$  (ATLAS: OK, CMS: no, Tevatron: no)

# Alternative interpretation: $M_H = 125$ GeV

- Viable to have the heavier CP-even MSSM Higgs boson at 125 GeV?  
-> Yes, but in a limited region of parameter space!

- In these scenarios the lightest Higgs is always *below* the LEP limit (with reduced couplings) -> LHC limits for lower  $M_h$  interesting

# 125 GeV Higgs: future prospects

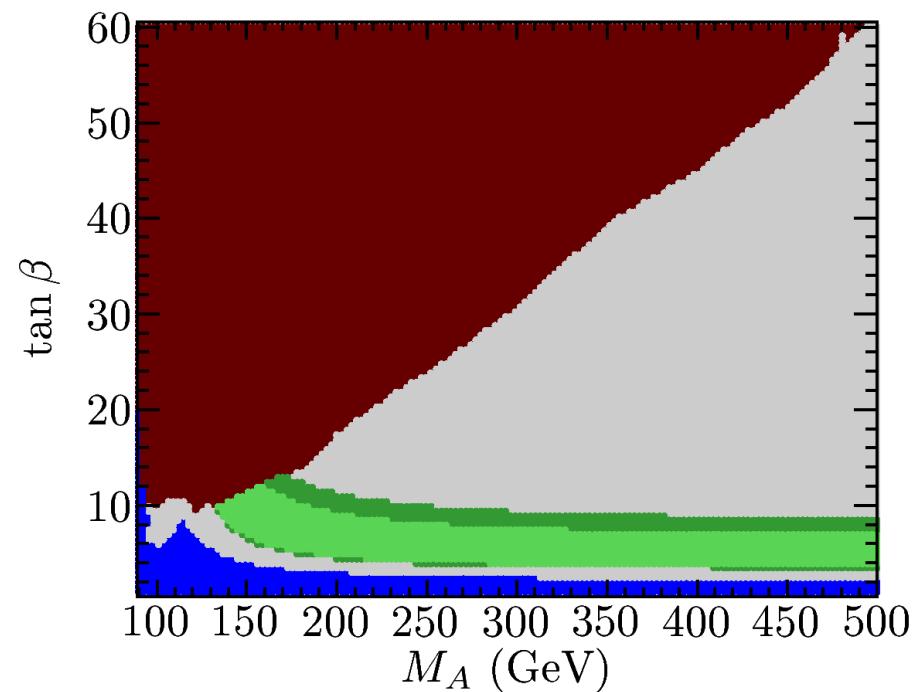

- Assuming something interesting at 125 GeV: Higgs? SM? MSSM?

## Establishing Higgs mechanism

Mass	LHC
Quantum numbers	LHC
Couplings	(LHC)/ILC
Self-couplings	(ILC)

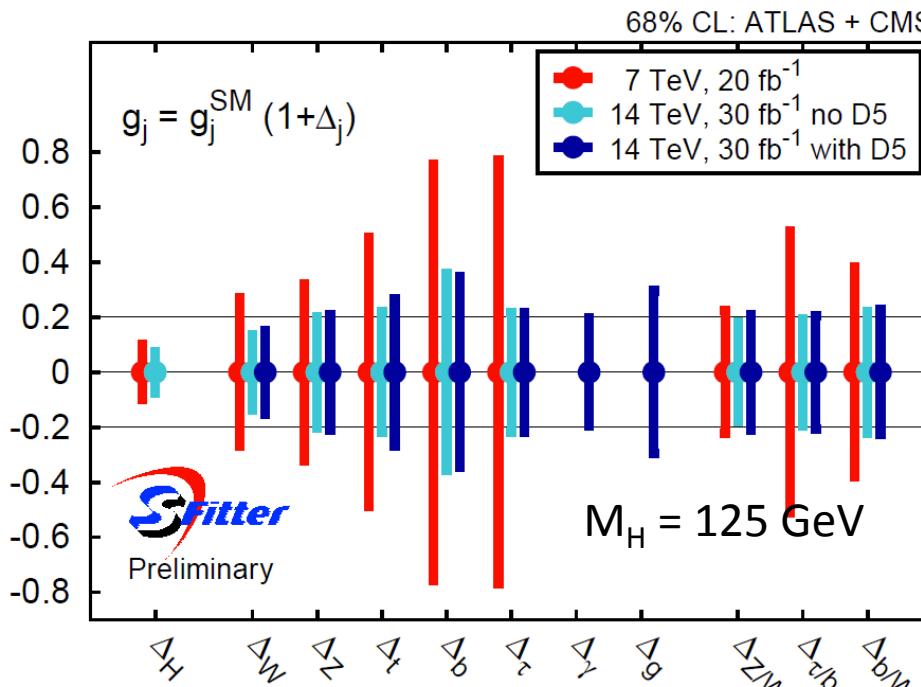

## Identifying SUSY

Direct obs.	LHC
(Heavy) Higgs obs.	LHC
Properties	ILC
Indirect meas. ( $M_W$ , ...)	ILC

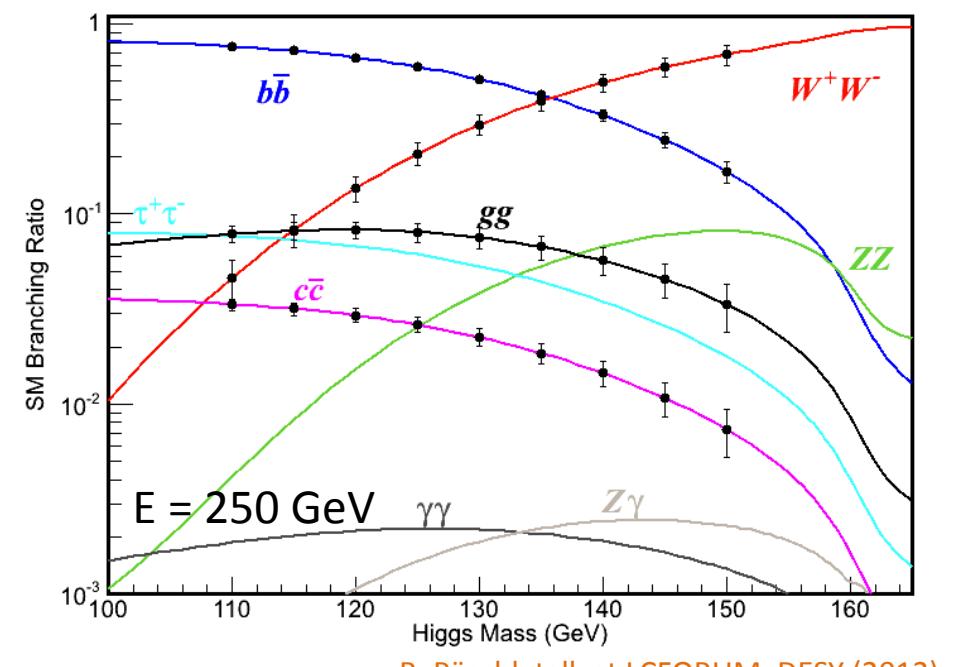

# 125 GeV Higgs: couplings

- A Higgs boson at 125 GeV is great news both for the LHC and the ILC(250). Wide range of modes accessible.
- Precise coupling measurements crucial test of SM/BSM
- SUSY is more than just MSSM (e.g. additional singlet as in NMSSM)

2012-04-25

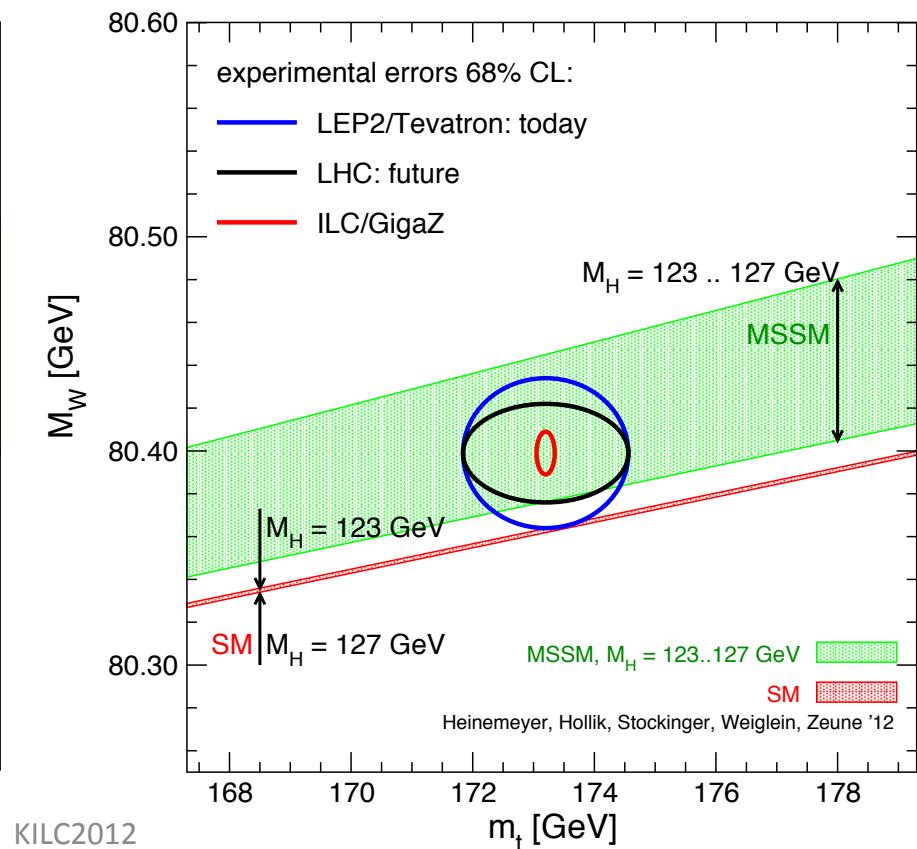

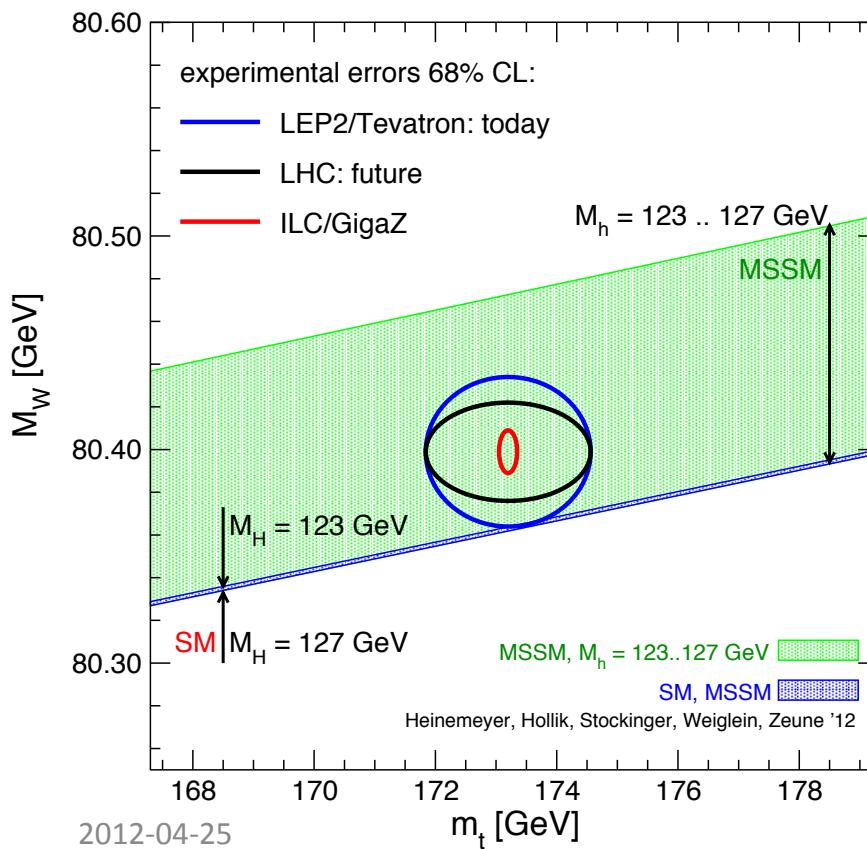

KILC2012

19

# Precision measurements: $M_W$

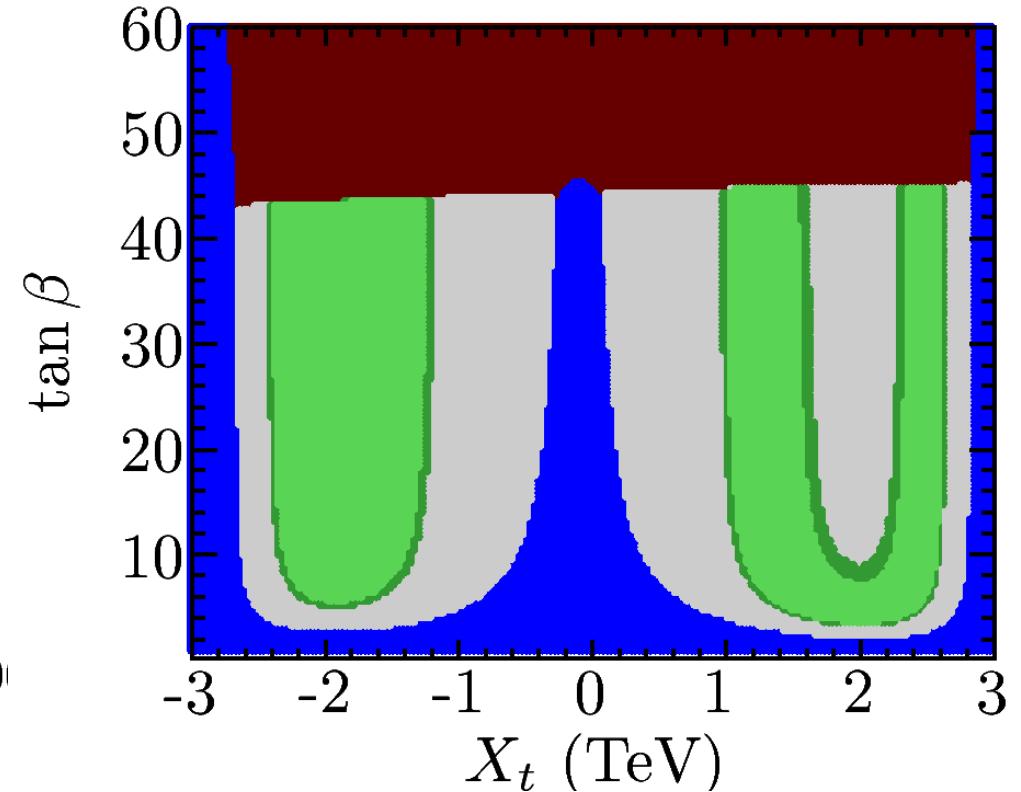

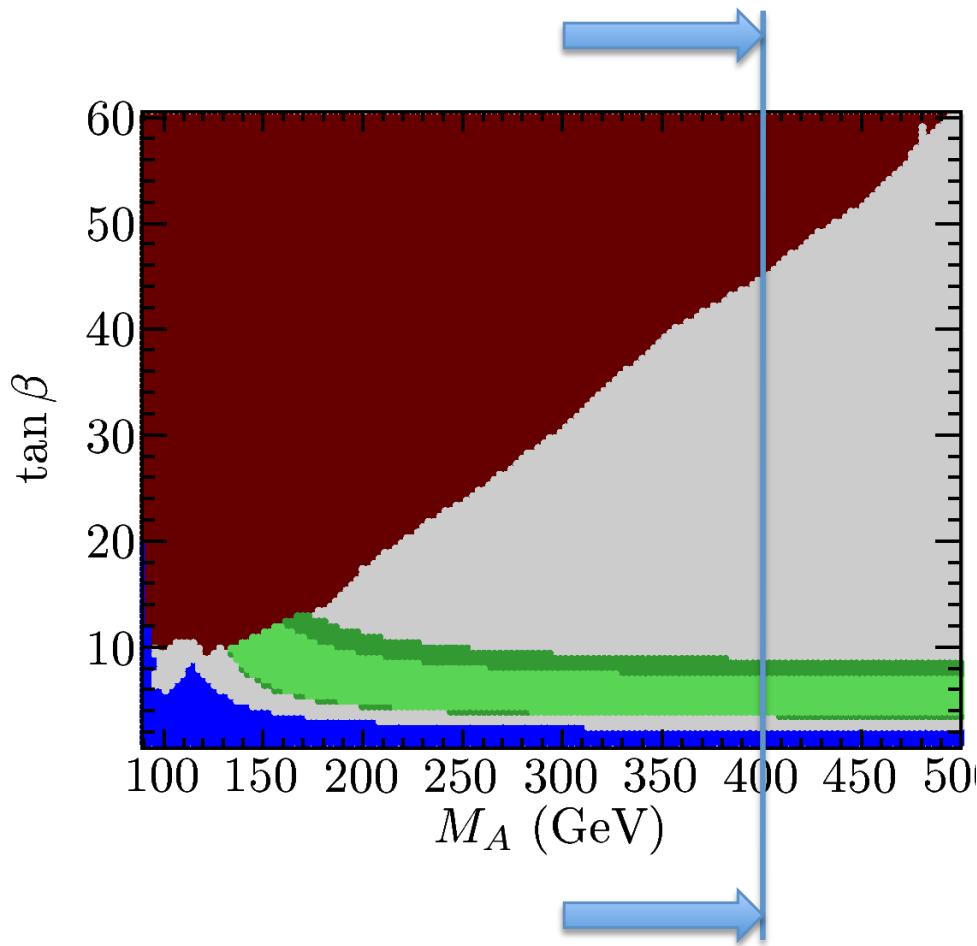

- Indirect measurements can point the way beyond the SM even in the case of “only” a light Higgs discovery at the LHC
- 2-loop  $M_W$  evaluation in MSSM, scan over 14 parameters  
Current experimental bounds + “Higgs signal” applied

# Conclusions

- LHC Higgs searches are rapidly becoming interesting to probe physics beyond the Standard Model.  
A large part of the MSSM ( $m_A$ ,  $\tan \beta$ ) plane is already excluded
- Two possible MSSM interpretations of a 125 GeV excess:  
 $M_h = 125 \text{ GeV}$  -> New lower limits on tree-level parameters  
 $M_H = 125 \text{ GeV}$  -> Small corner of parameter space still viable
- Observed rates compatible with SM, suggests decoupling limit  
Enhanced  $h \rightarrow \gamma\gamma$  still an open possibility in the MSSM
- At 125 GeV, the LHC has access to several Higgs couplings.  
The ILC could provide precision for model discrimination.
- No new physics at LHC -> precision measurements

# Upper limit on tree-level parameters?

Maximal mixing gives the model-independent lower bound on  $\tan \beta$ , but the most stringent upper bound possible.

## Parameter ranges MSSM scan

Parameter	Minimum	Maximum
$M_{\text{SUSY}}$	750	1500
$M_2 \simeq 2M_1$	200	500
$A_t = A_b = A_\tau$	-2400	2400
$\mu$	200	3000
$M_A$	100	600
$\tan \beta$	1	60
