

Physics Studies for a Staged Construction of CLIC

Frank Simon
for the CLIC Physics and Detector Study

MPI for Physics, Munich, Germany
Excellence Cluster 'Universe', Munich, Germany

with thanks to all those who contributed to the CLIC studies

KILC12, Daegu, Korea, April 2012

Max-Planck-Institut für Physik
(Werner-Heisenberg-Institut)

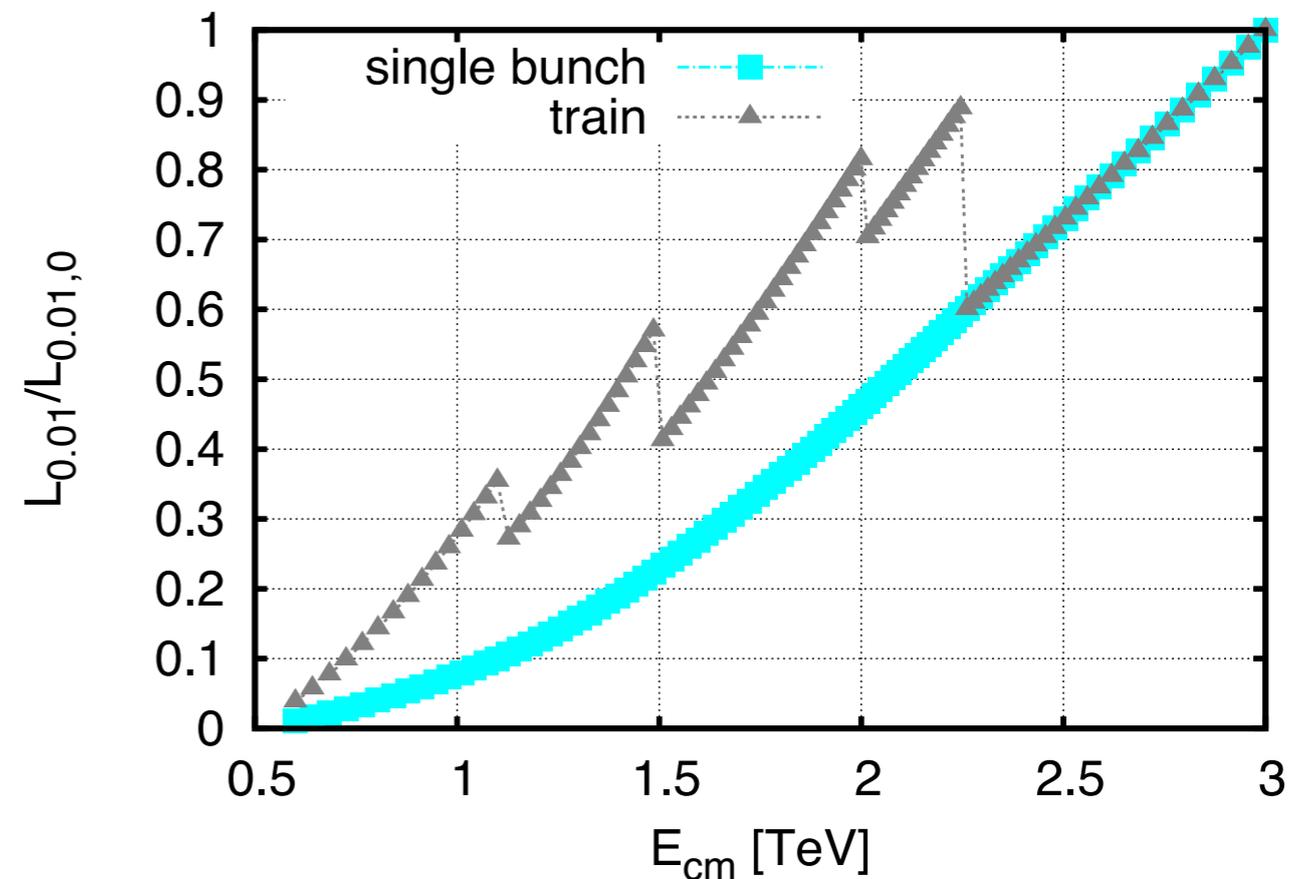

Outline

- CLIC - Staged Implementation
- Benchmark processes - Physics in Stages
- “Guaranteed Physics”: Higgs & Top
- Beyond the Standard Model: SUSY
- Summary / Outlook

Motivation

- Interesting physics (may) exists at various energies:
 - Few 100 GeV: (almost) guaranteed - SM - Higgs, Top
 - Still unknown: BSM physics, potentially various thresholds in the few 100 GeV to few TeV - region
 - ▶ Need high luminosity for low and high energies!
- Significant luminosity penalty when operating far below design energy (is mitigated by changing bunch train length, but more than a factor 3 in energy is impractical)
- Start with physics during construction phase for higher energies

Staged Construction of CLIC

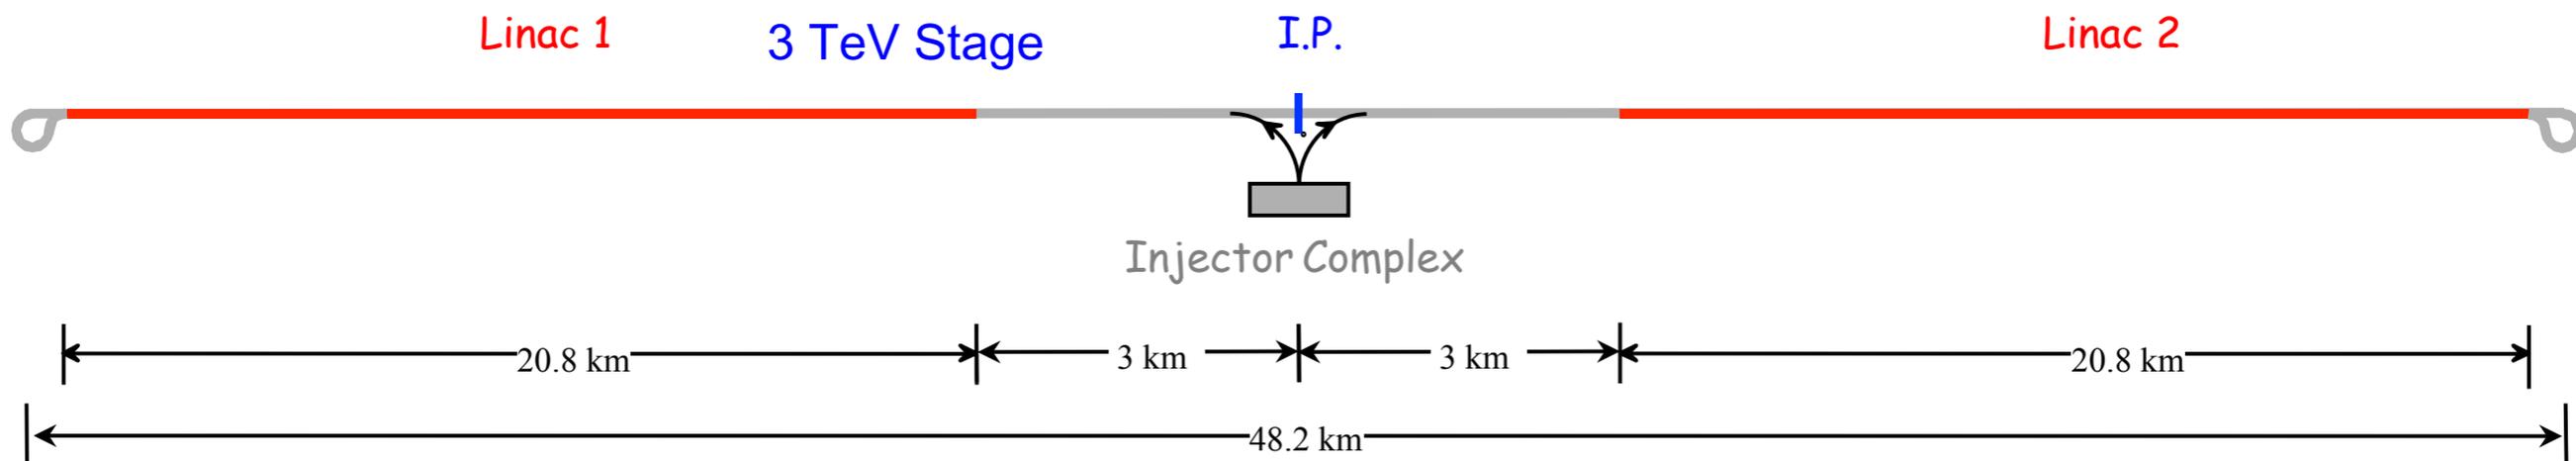

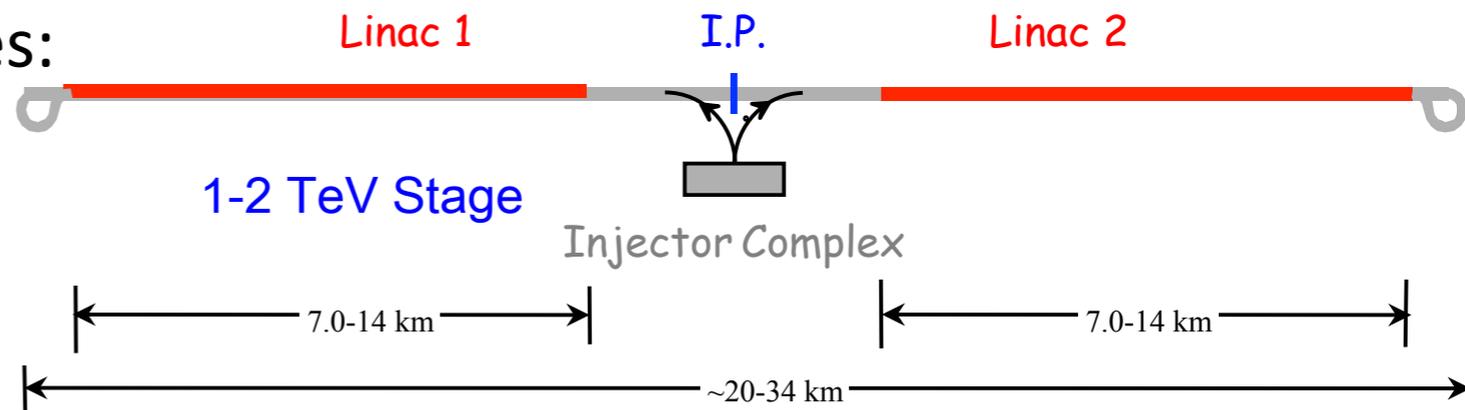

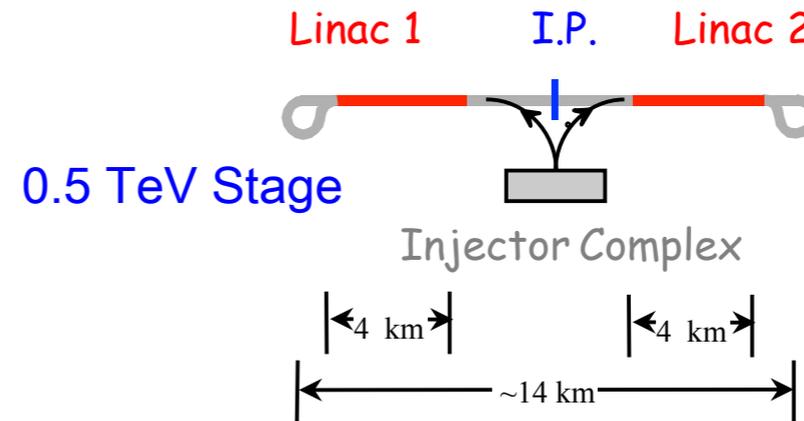

- Realistic scenario:

3 energy stages, exact energies to be determined by future results

- A 1.4 TeV CLIC requires only one drive beam complex: A natural intermediate stage

- Assumptions for benchmark studies:

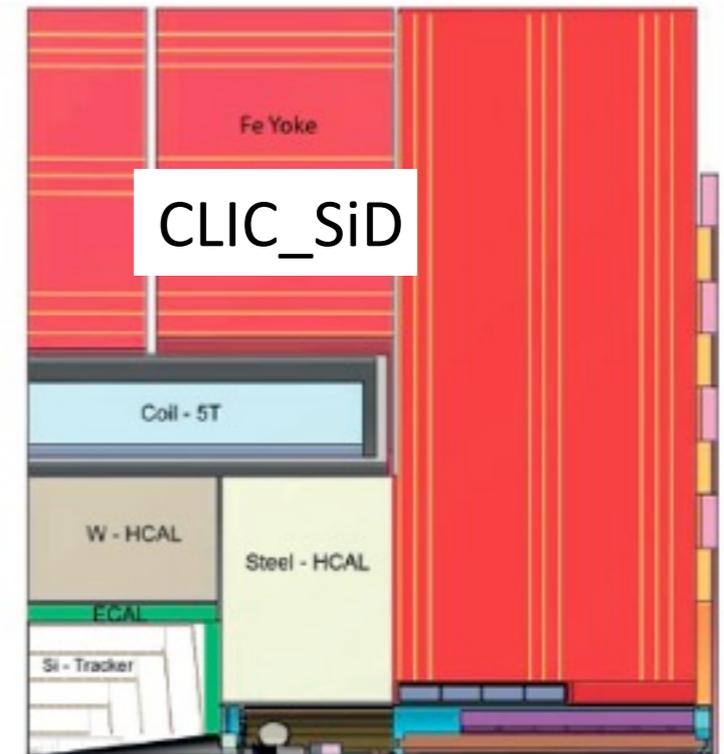

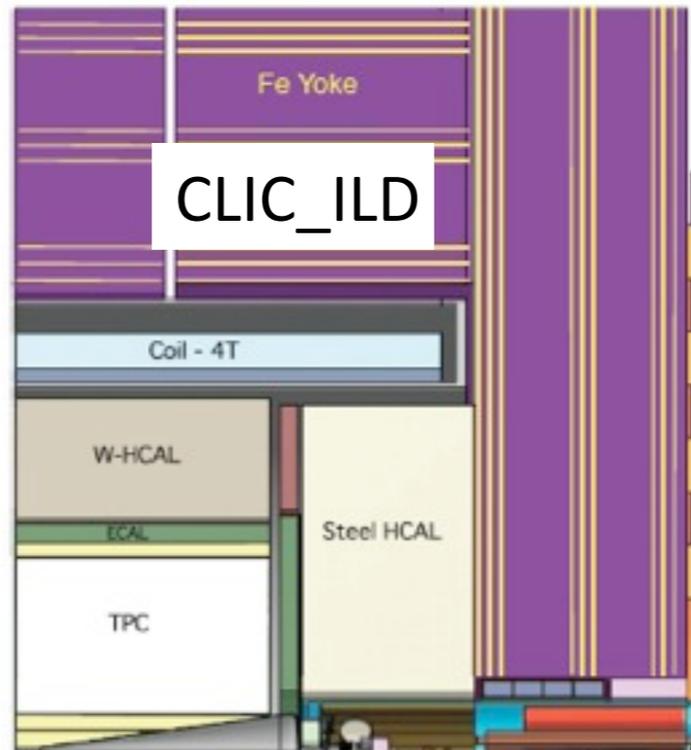

- 500 GeV: 500 fb⁻¹
- 1.4 TeV: 1.5 ab⁻¹
- 3 TeV: 2 ab⁻¹

Detectors and Experimental Environment at CLIC

- Detectors based on ILC concepts - With energy and environment-specific modifications:

- deeper HCAL
- precision timing
- modified vertex detector
- redesigned forward region

- Main event reconstruction challenge:

Pile-up of $\gamma\gamma \rightarrow$ hadrons mini-jet events

- Included in simulation studies by overlaying $\gamma\gamma \rightarrow$ hadrons events on physics events
- Rejected by timing and/or p_t cuts

Varies significantly with energy

Hadron events above 2 GeV:

350 GeV: 0.05 / BX

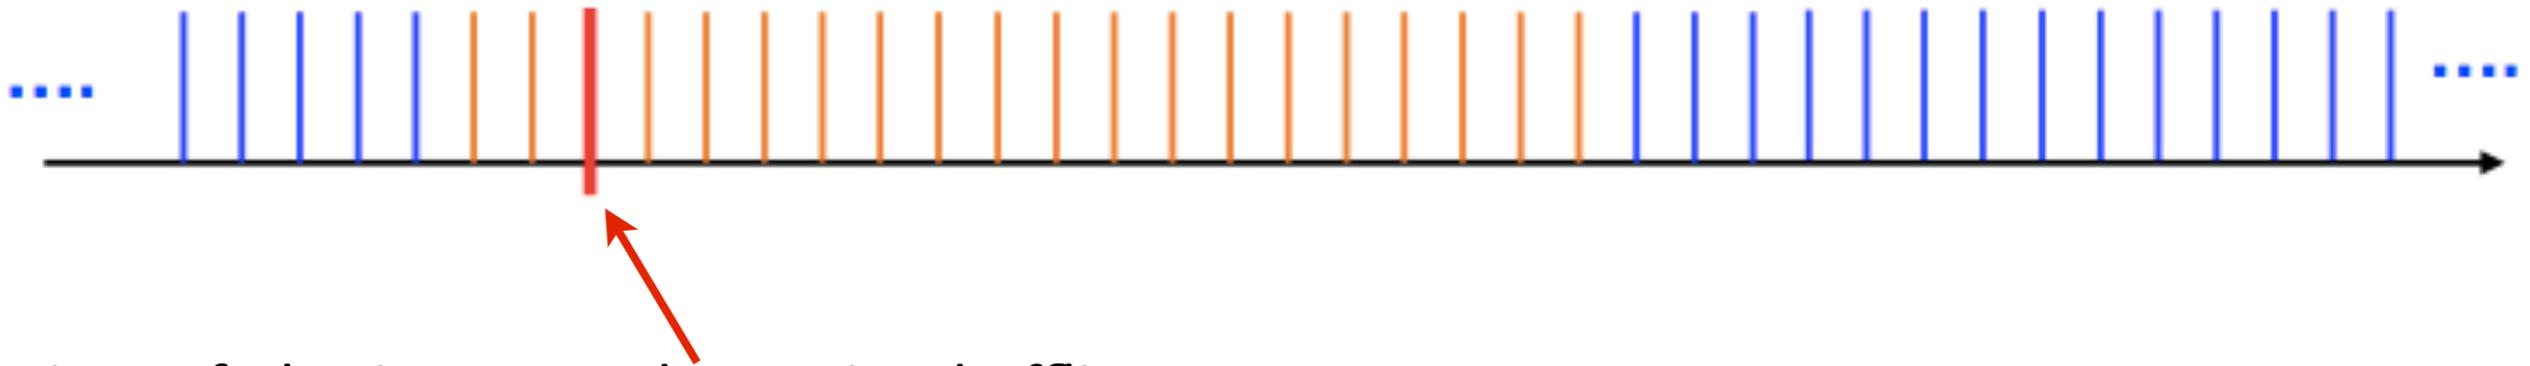

500 GeV: 0.3 / BX

1.4 TeV: 1.3 / BX

3 TeV: 3.2 / BX

Event Reconstruction & Timing Cuts

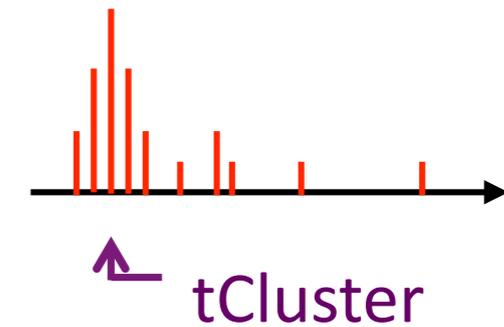

- Triggerless readout of bunchtrain

- Time of physics event determined offline

- Use timing information from all detector subsystems to determine time of individual clusters and particles

Calorimeters of particular importance!

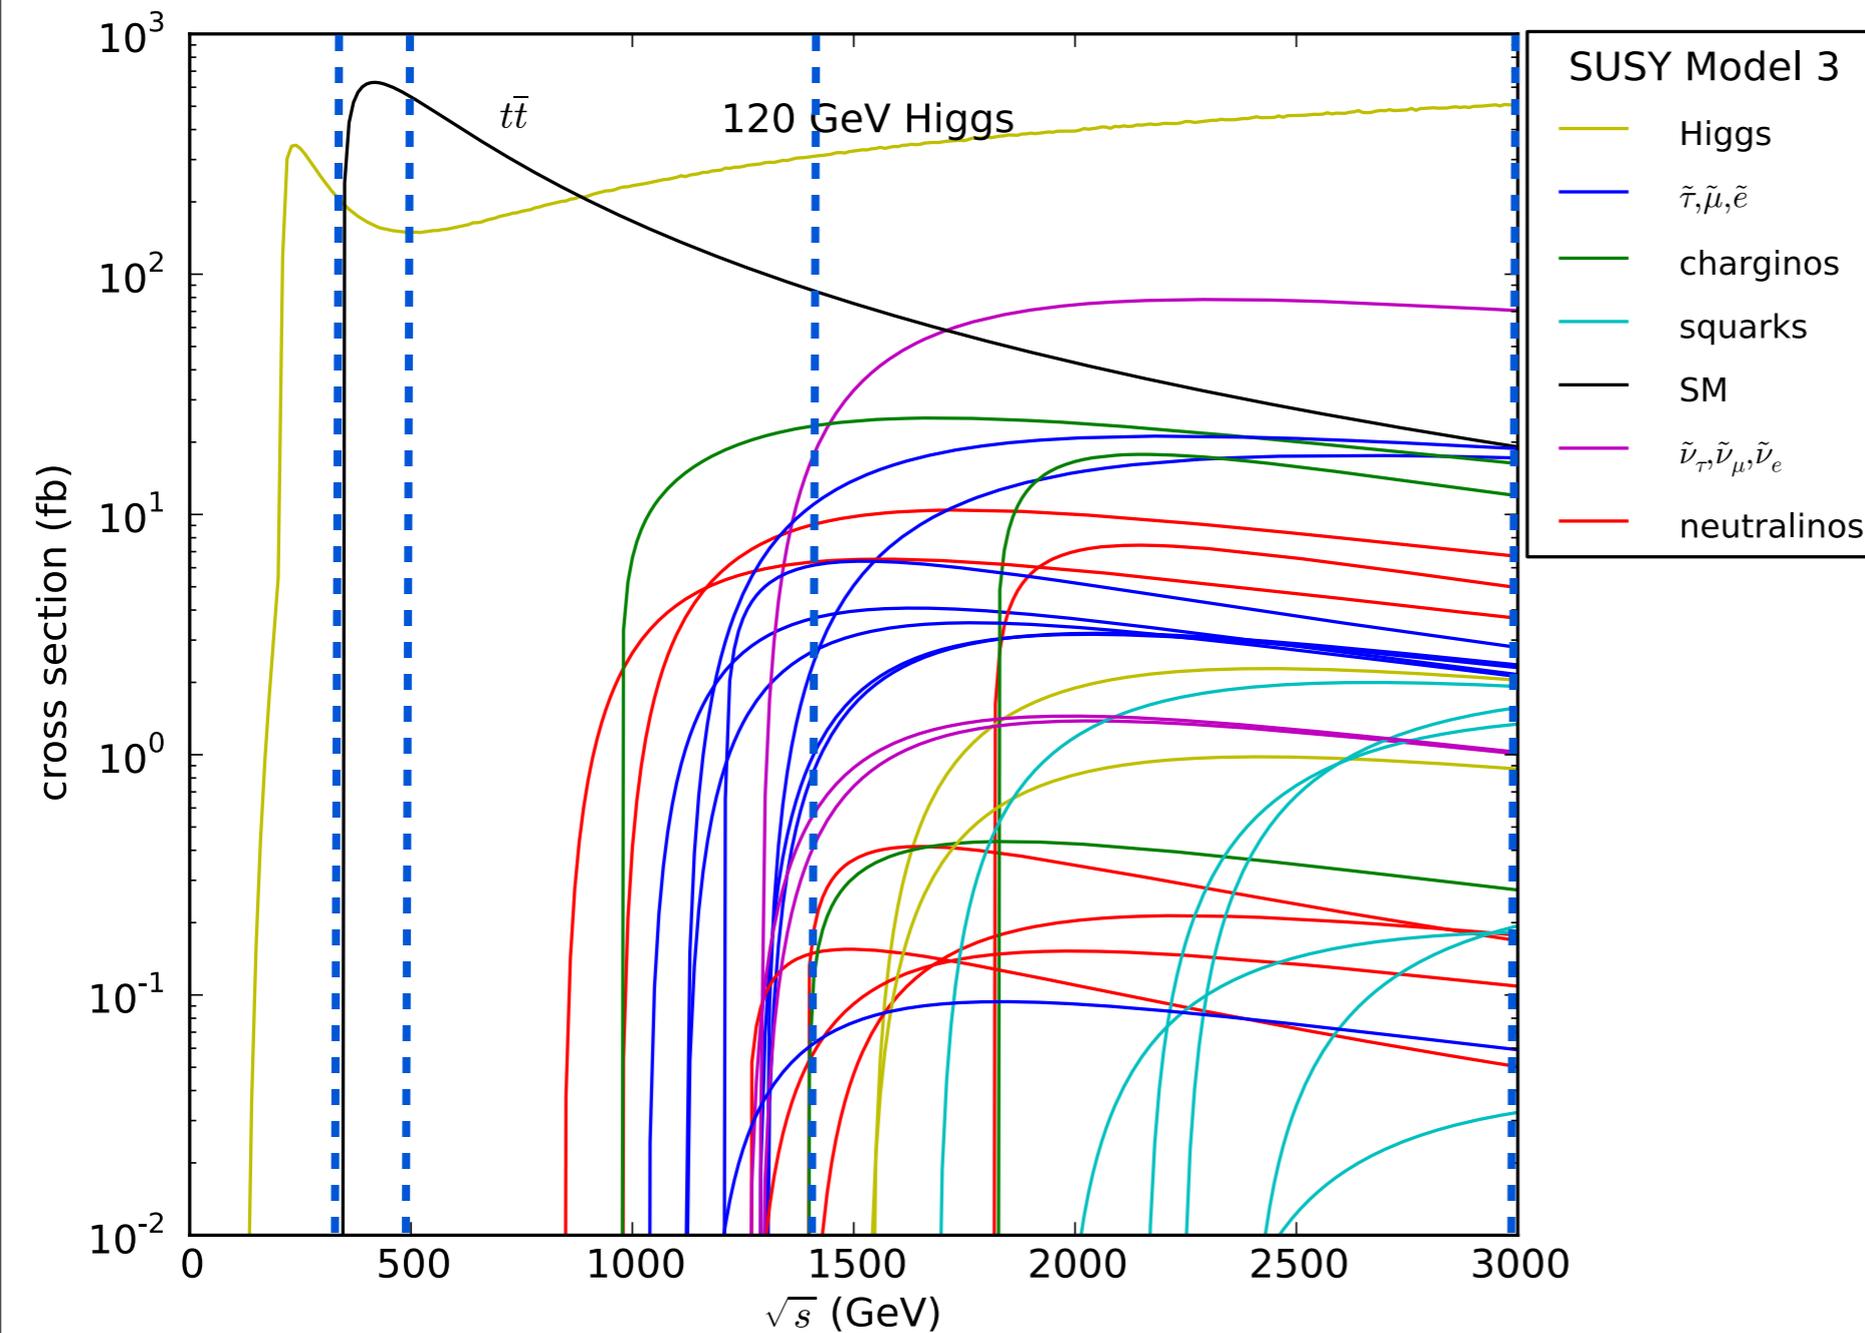

- Cluster-based timing cuts & p_T cuts to reject background

- Event reconstruction with PFA using timing information

- Use well-adapted jet finding algorithms to further mitigate effects of background

- based on LHC experience (FastJet)

Benchmark Studies: Physics in Stages

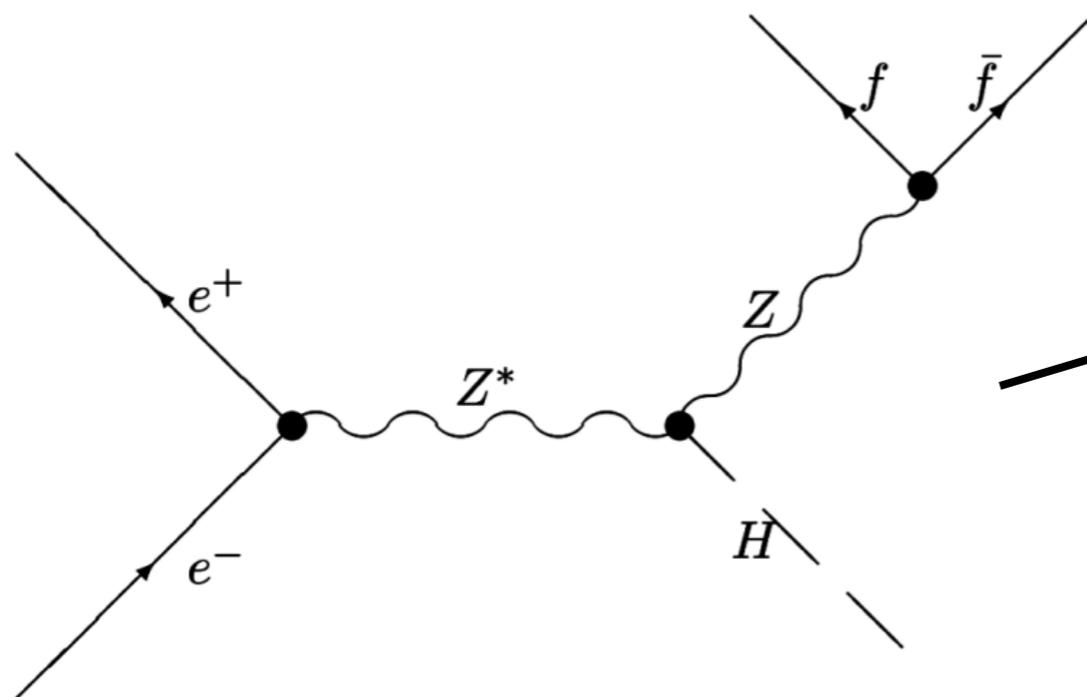

- 500 GeV machine
 - Top threshold scan
 - Top mass in continuum
 - Higgs mass, BR
- 1.4 TeV machine
 - Higgs selfcoupling
 - Various SUSY studies in specific model (Model III)
- 3 TeV machine
 - Higgs selfcoupling
 - Various SUSY studies in Physics & Detectors CDR SUSY model

Standard Model

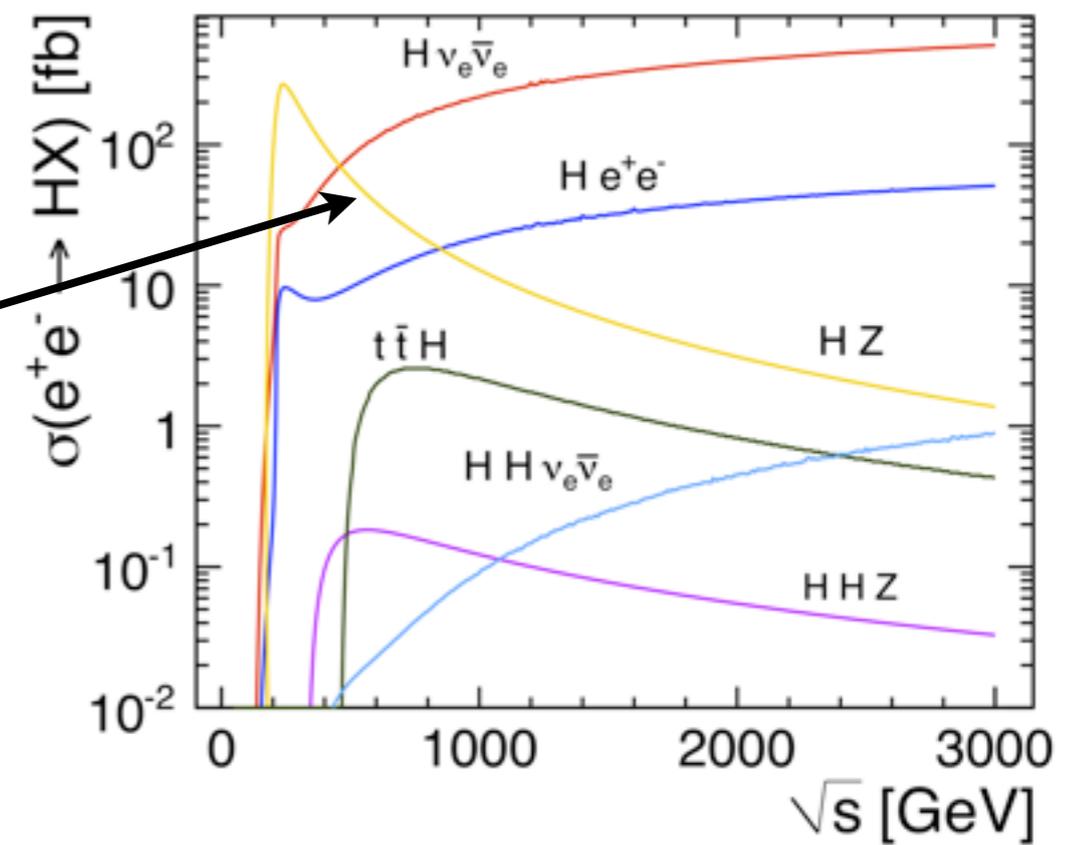

Higgs - Model-Independent Mass & Branching Ratios

- Measurement of Higgs mass and cross section in Z recoil:
 - No built-in assumption on Higgs decay modes
 - ▶ Allows to detect invisible decay modes by precise cross section measurements and comparison to visible decays

Difficult significantly above threshold:

- Low cross section
- Reduced resolution for leptons from Z decay
- Higher SM background

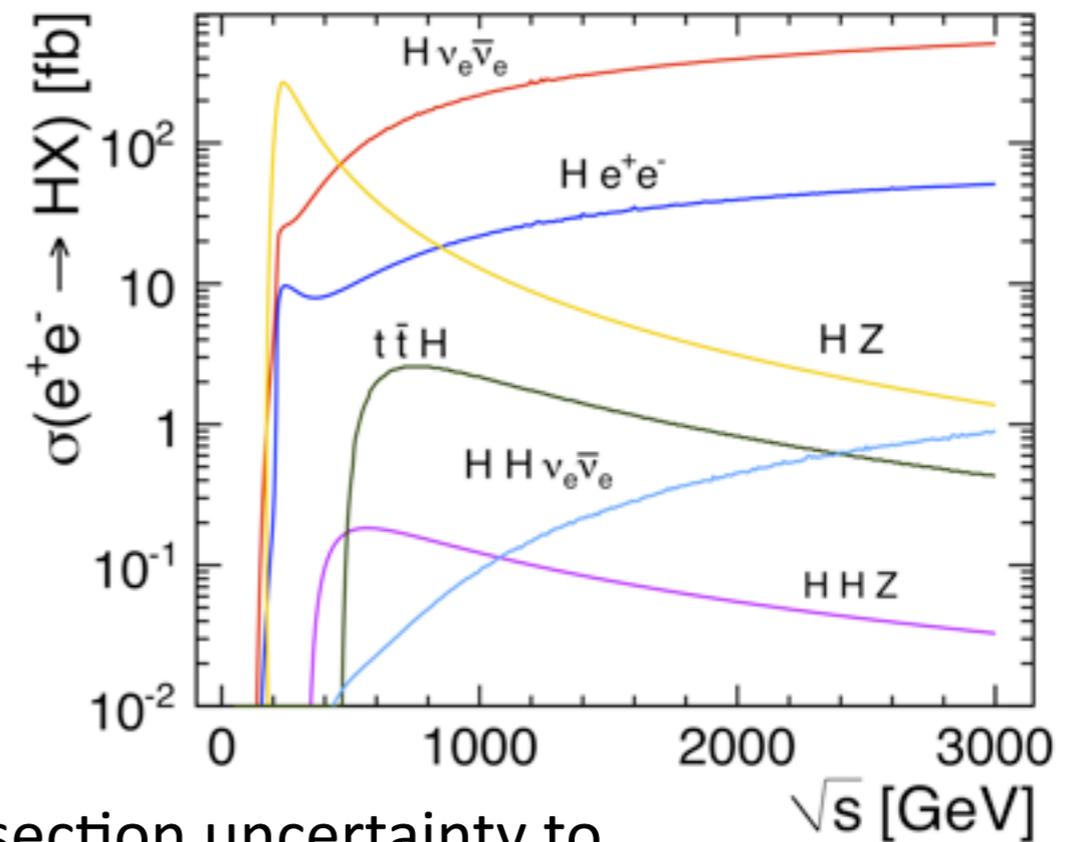

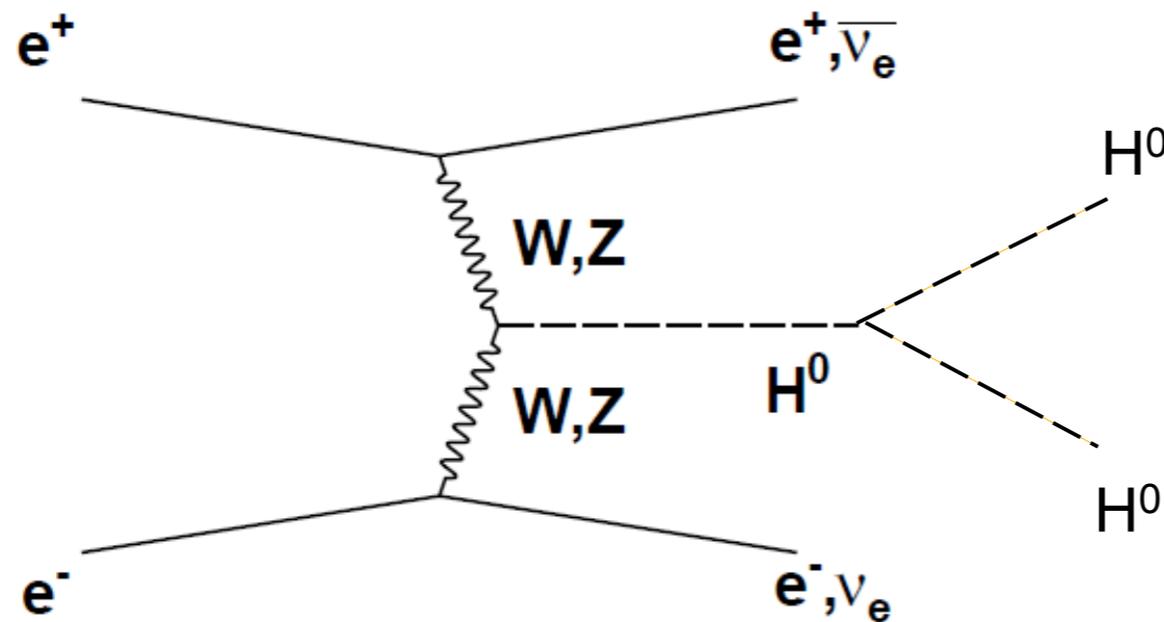

Perform study at 500 GeV and 350 GeV:
Work in progress!

Higgs - Selfcoupling

- Measurement of the trilinear coupling λ

$m_h = 120 \text{ GeV}$

- At energies above 1 TeV, WW fusion to HHvv final state dominates

- The measurement:
Cross section of HHvv

Relation of cross section uncertainty to trilinear coupling currently under investigation

$$\frac{\Delta\lambda_{hhh}}{\lambda_{hhh}} = x \cdot \frac{\Delta\sigma}{\sigma}$$

at 3 TeV: $x \sim 1.6$

at 1.4 TeV: $x \sim 1$

including ISR and BS

preliminary!

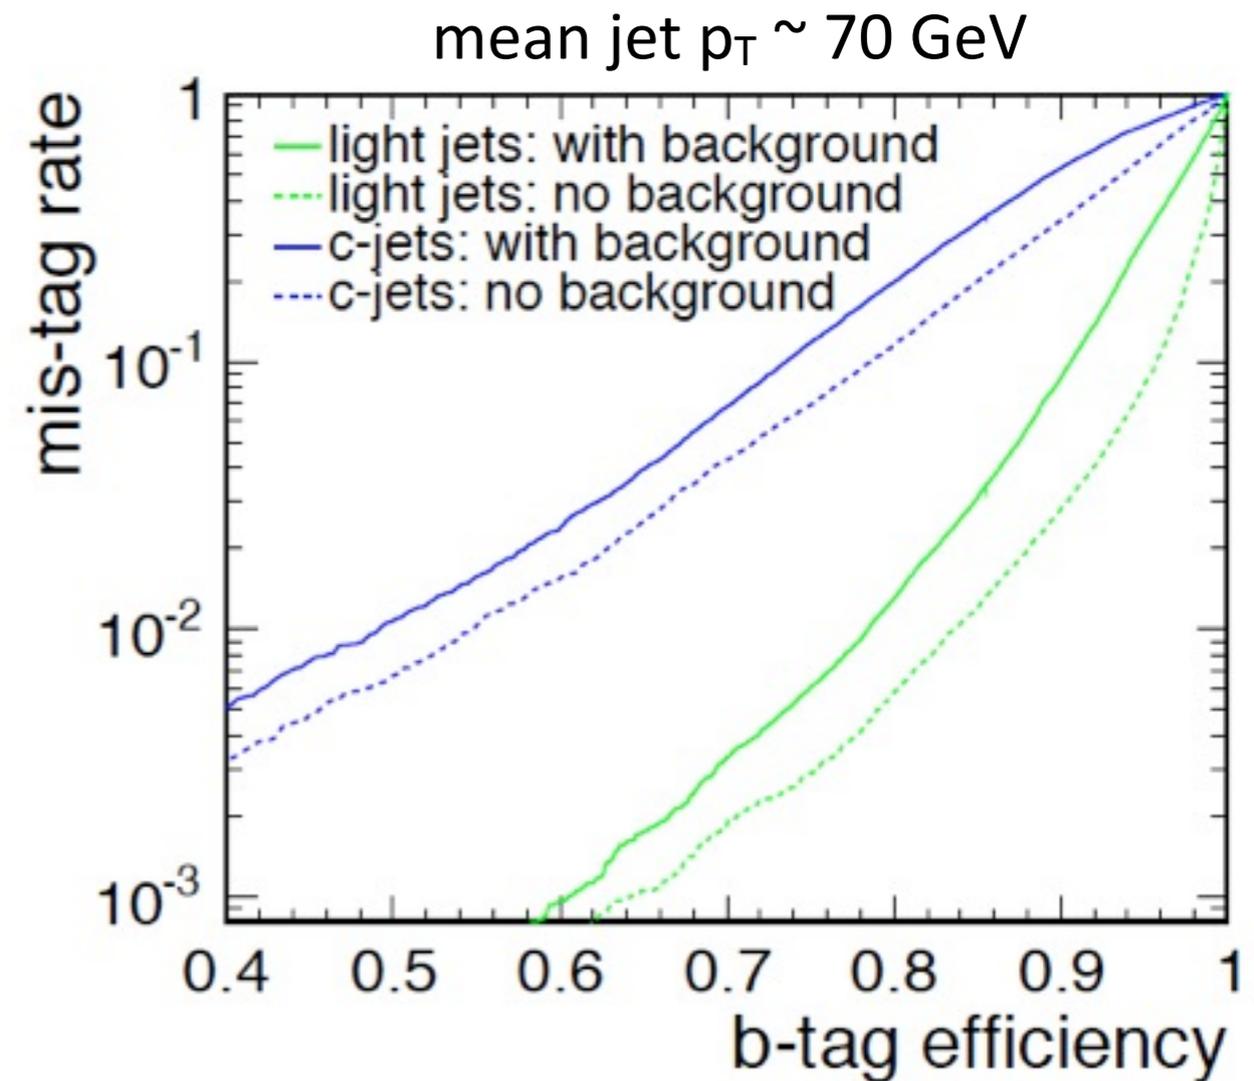

Higgs Selfcoupling at 1.4 TeV and 3 TeV

- Main challenges:
 - Small signal cross-section: ~ 0.9 fb
 - Large backgrounds
 - Quality of flavor tagging in presence of $\gamma\gamma \rightarrow$ hadrons pile-up

Higgs reconstruction in decay to b quarks-
Makes use of excellent flavor tagging

Work in progress:

Using Neural Network for background rejection
Extract cross section to determine λ

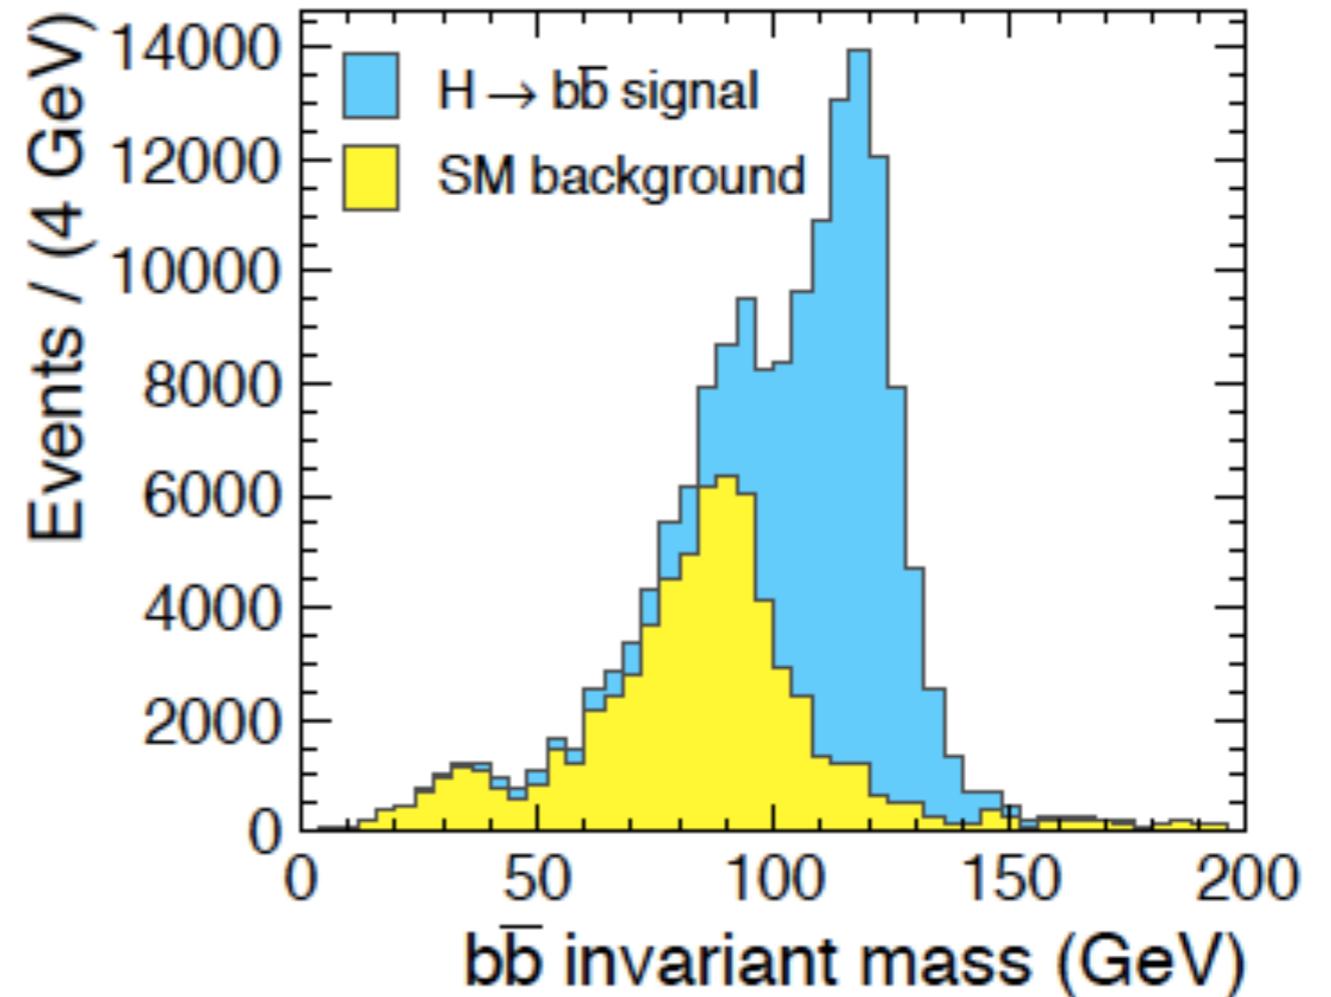

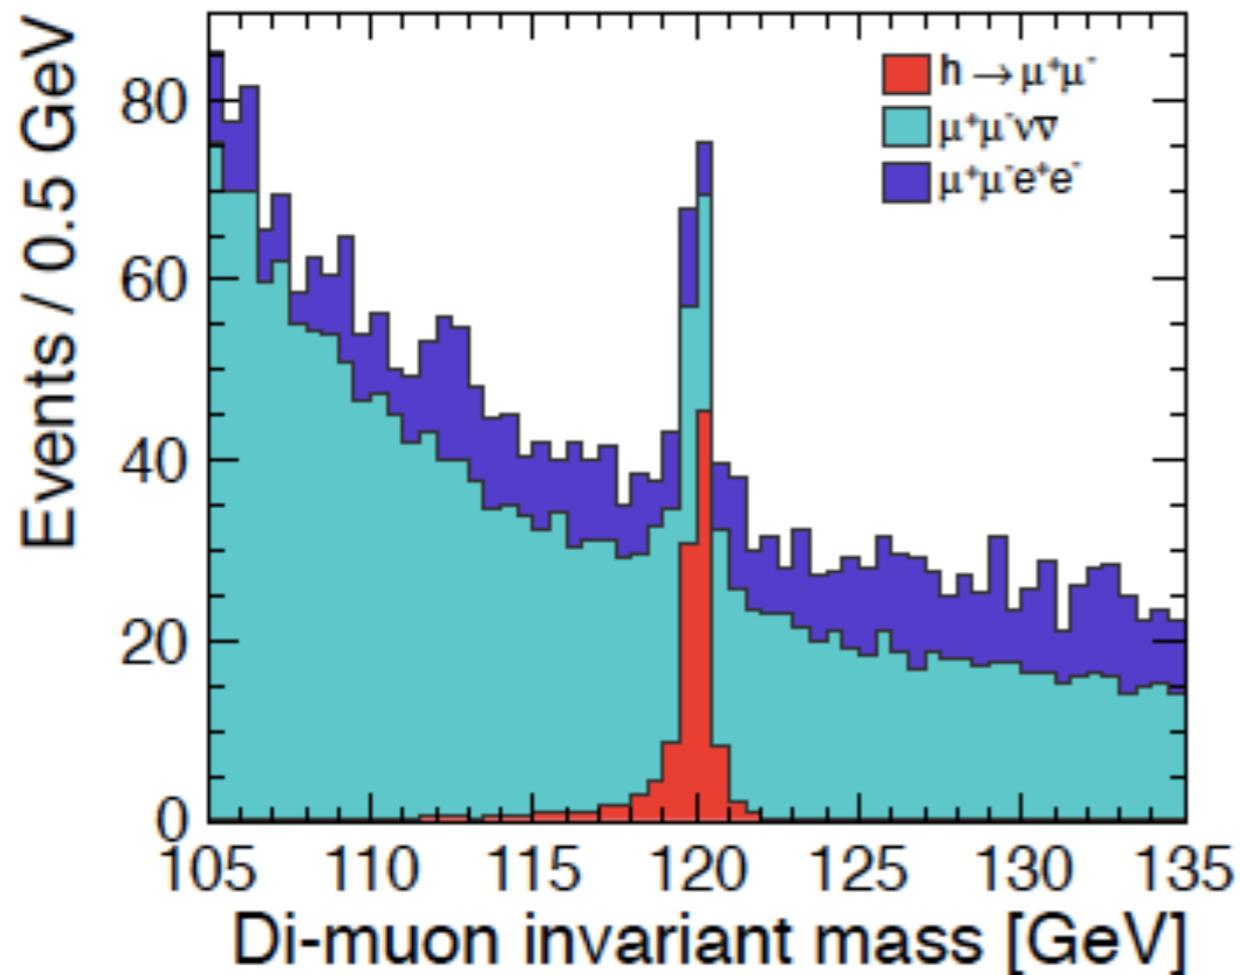

Efficient, high purity flavor tagging
also possible in presence of
background

Higgs Branching Fractions at 3 TeV

- Exploit high production cross section and high luminosity
- Measure also rare decays

15% stat. precision on $\sigma(H \rightarrow \mu\mu)$
requires forward electron tagging
to suppress background

0.22% stat. precision on $\sigma(H \rightarrow b\bar{b})$
3.2% stat. precision on $\sigma(H \rightarrow c\bar{c})$

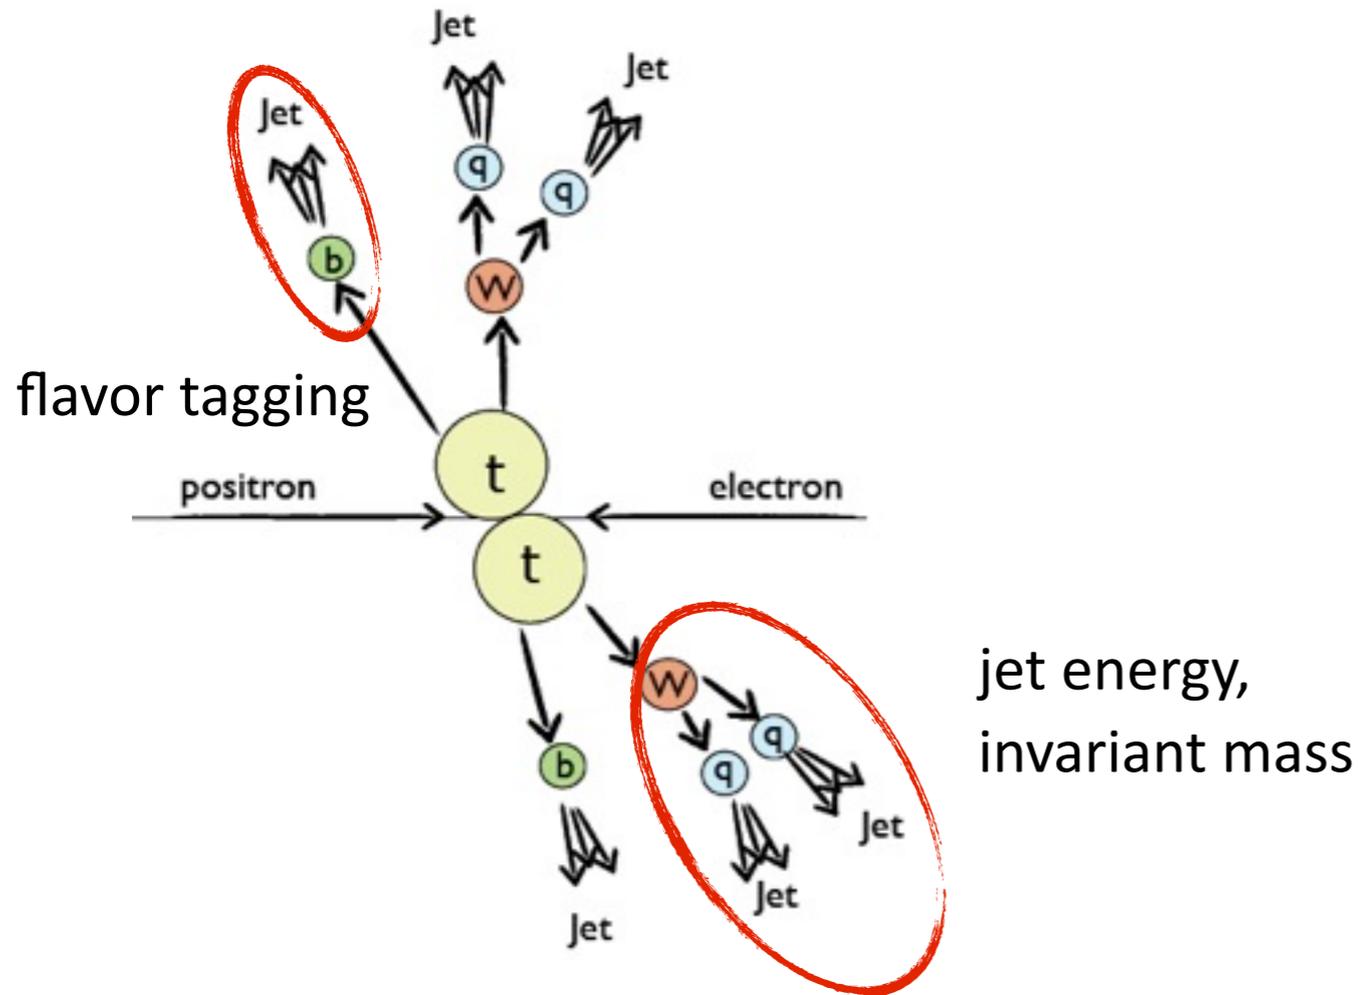

LCD-Note-2011-035, LCD-Note-2011-036

Top Mass Measurements at CLIC

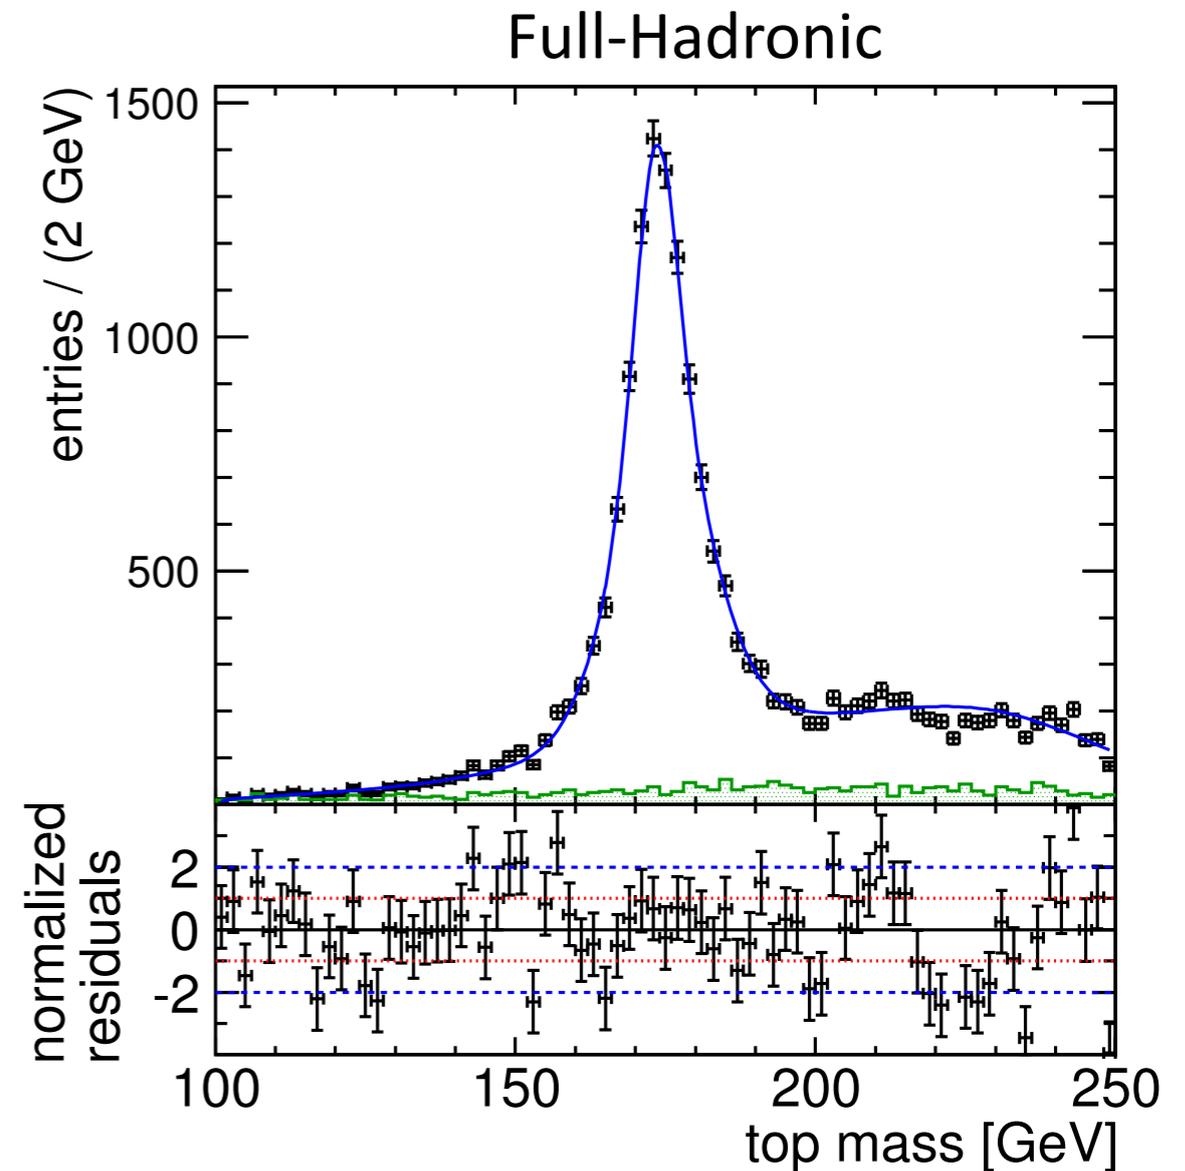

- Two approaches at Linear Colliders:
- Threshold scan:
 - Theoretically well understood
 - Measurement of top pair production cross section at several points around threshold
 - Requires dedicated operation of machine for extended period
- Mass measurement from invariant mass of decay products:
 - Theoretically problematic (experiments measure “event generator top mass”, treatment of QCD corrections ill-defined) - progress is being made
 - Requires excellent jet and lepton reconstruction, helped by kinematic constraints
 - Can be performed at arbitrary energy above threshold - does not compete with other measurements, high integrated luminosity unproblematic

Top Mass from Invariant Mass of Decay Products

- Measurement of top pairs at 500 GeV
 - Kinematic fit to optimize mass resolution - also serves as background rejection

- Top mass stat. error with 100 fb^{-1} :
80 (90) MeV all-hadronic (semi-leptonic)

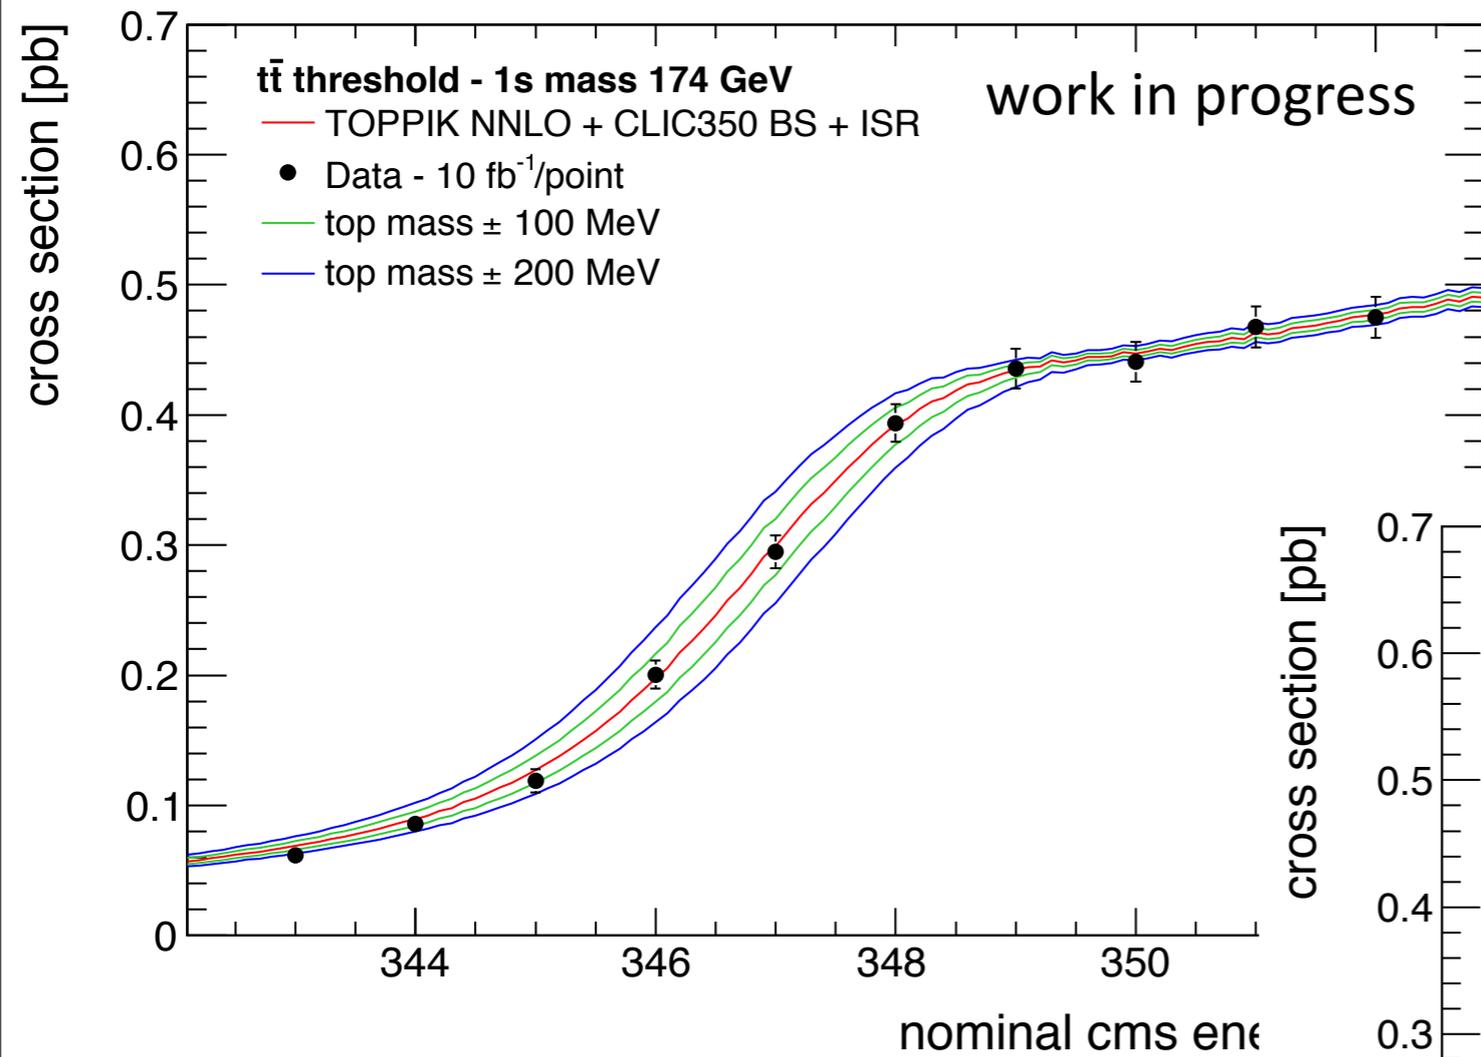

LCD-Note-2011-026

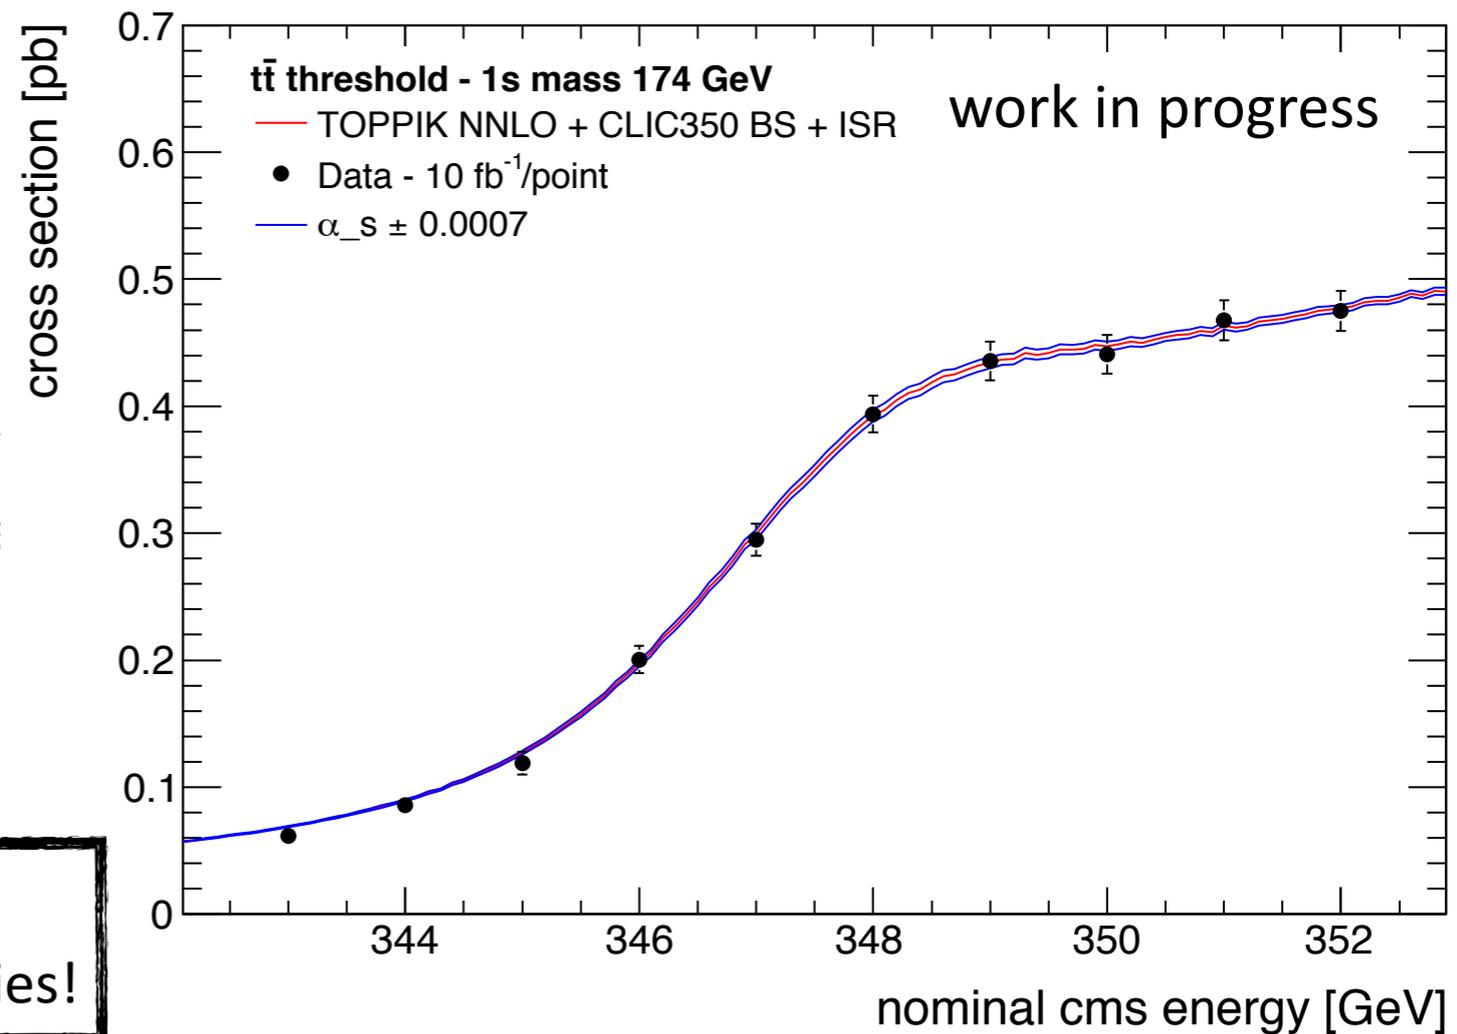

Top Threshold Scan

- Running the 500 GeV machine at around 350 GeV allows to scan the $t\bar{t}$ threshold
- Strategy of the study:
 - NNLO calculations of the $t\bar{t}$ threshold with TOPPIK (A.Hoang, T. Teubner): provides the production cross section
 - Full simulations of top pairs slightly above threshold in PYTHIA to obtain efficiencies, background rejection - Includes overlay of $\gamma\gamma \rightarrow$ hadrons
 - Top mass extracted from a fit of the background-subtracted cross section, fit based on NNLO calculations
- Current status:
 - NNLO calculations (including ISR and CLIC beamspectrum at 350 GeV) available
 - Full simulation of signal and background with overlay ongoing:
Currently using selection efficiency at 500 GeV, with background levels scaled to 350 GeV (increase with $1/s$) to get first impression of sensitivities

Top Threshold - Mass Sensitivity at CLIC

- High sensitivity to top mass in the turn-on region: Possibility for optimized choice of energy points

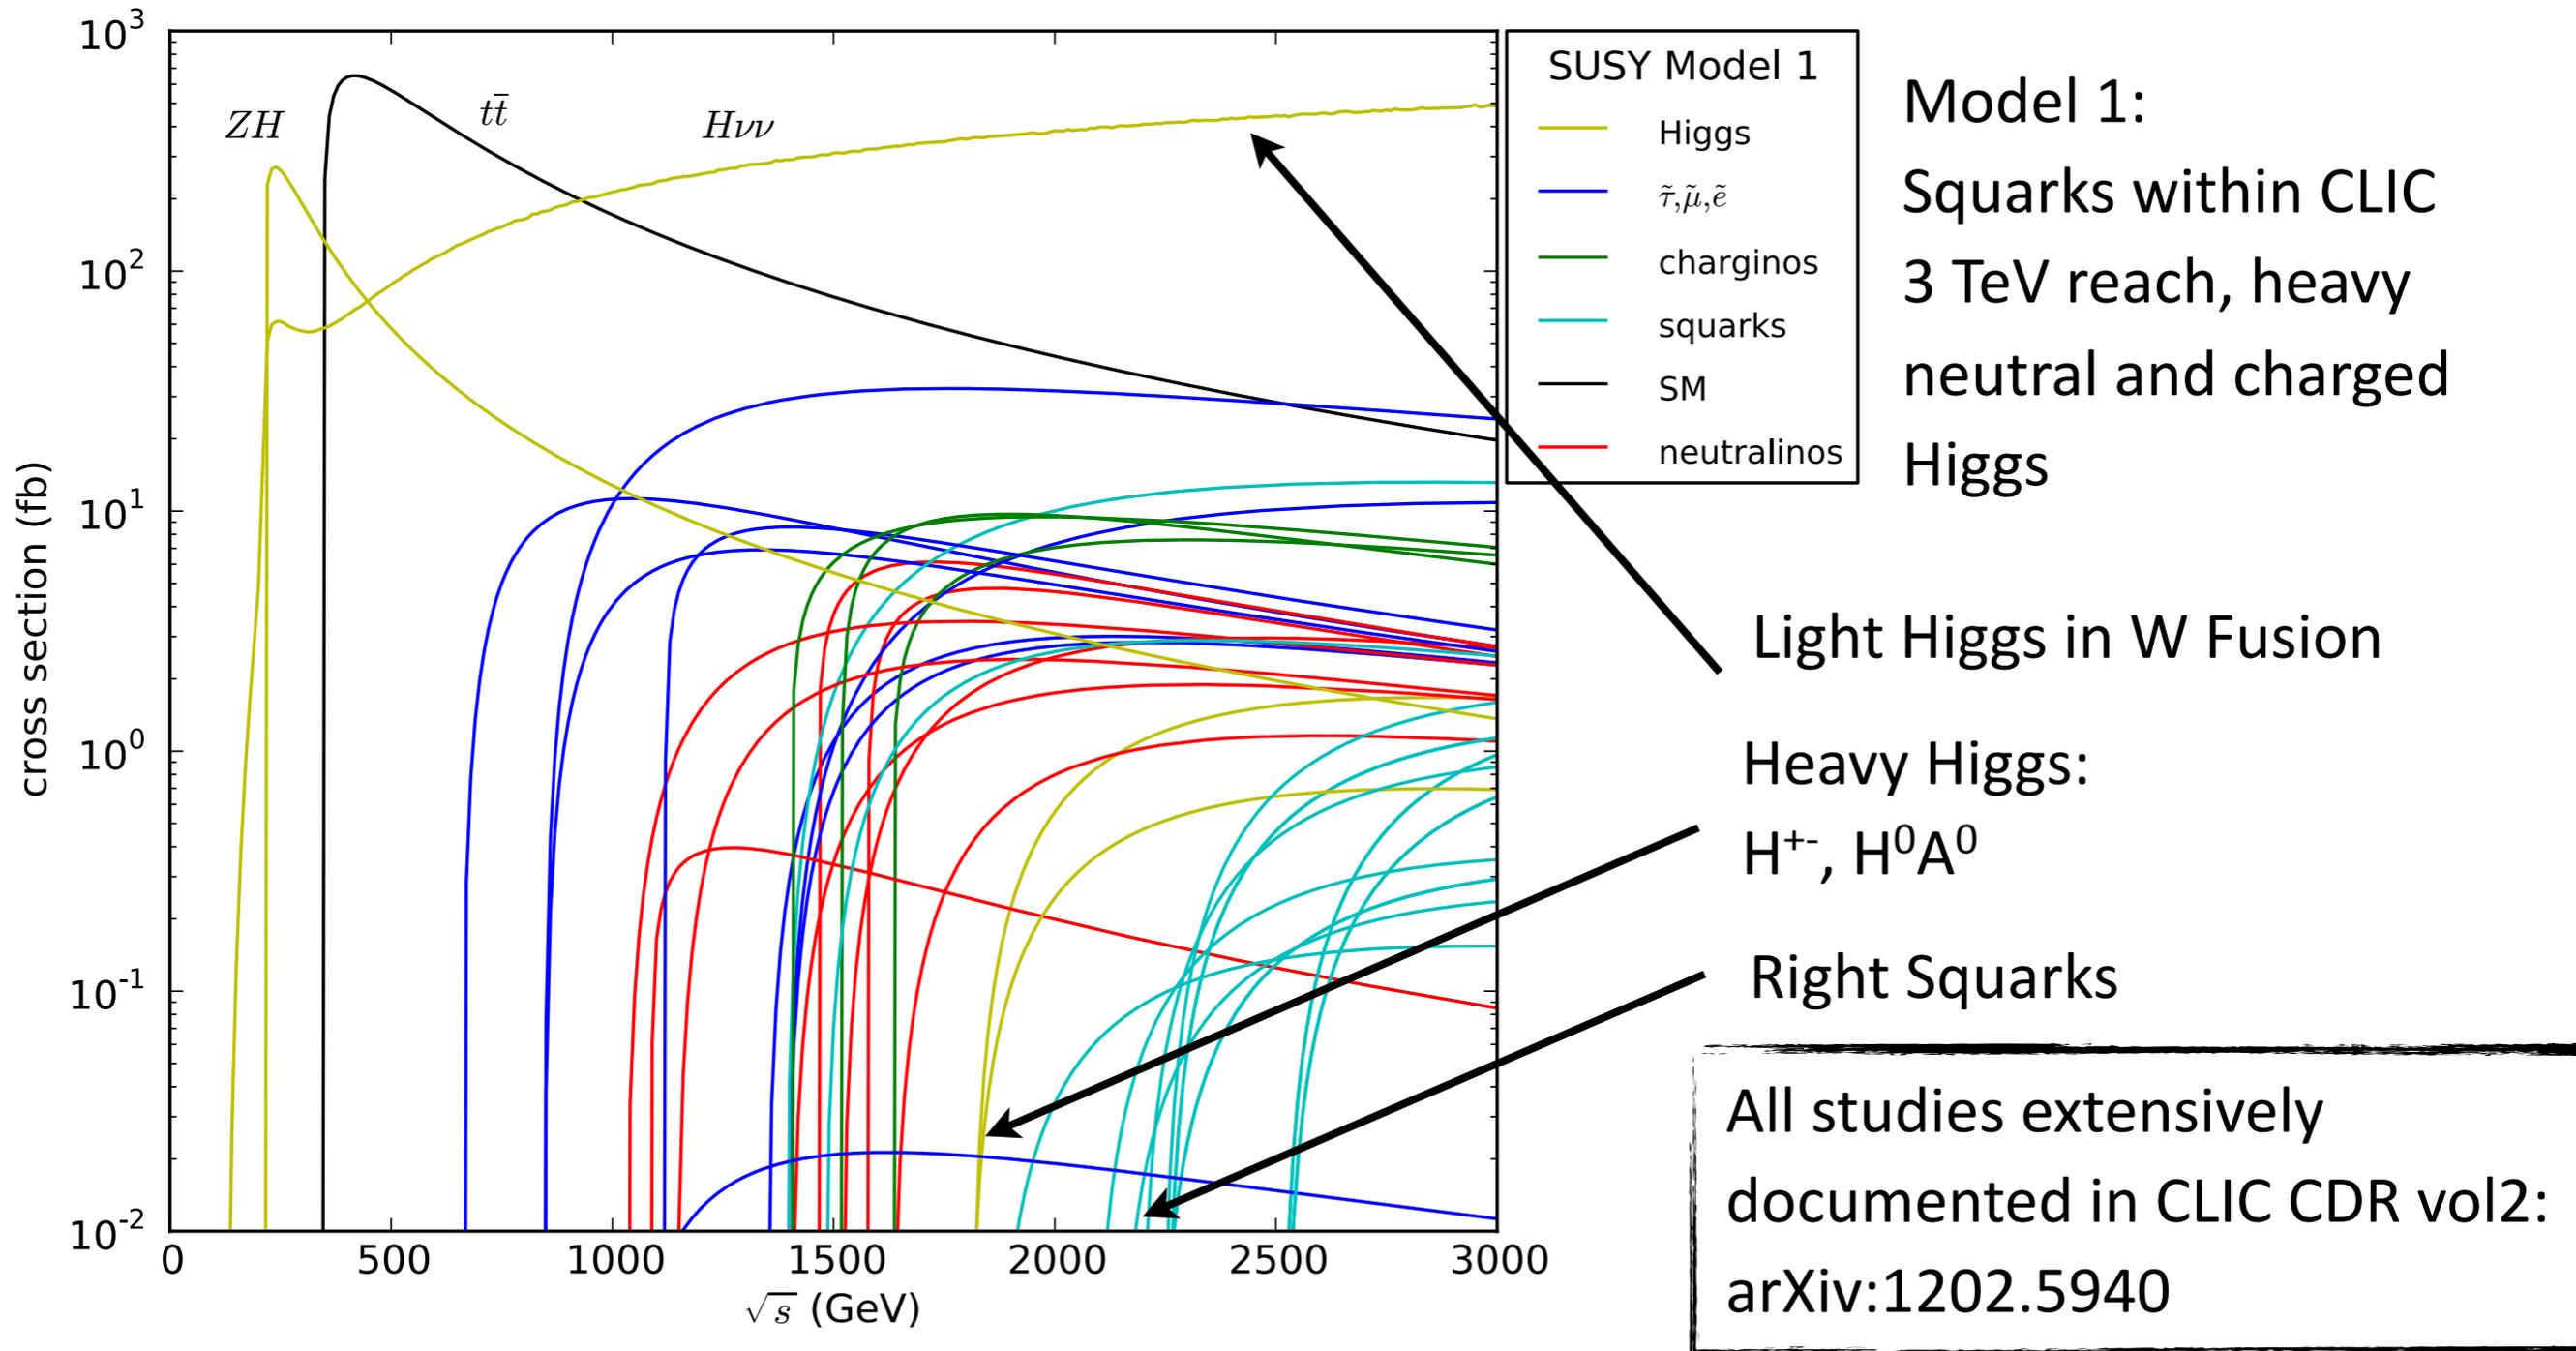

- Sensitivity also to α_s , but error on current world average already hard to beat

preliminary:
500 GeV selection efficiencies!

Beyond the Standard Model

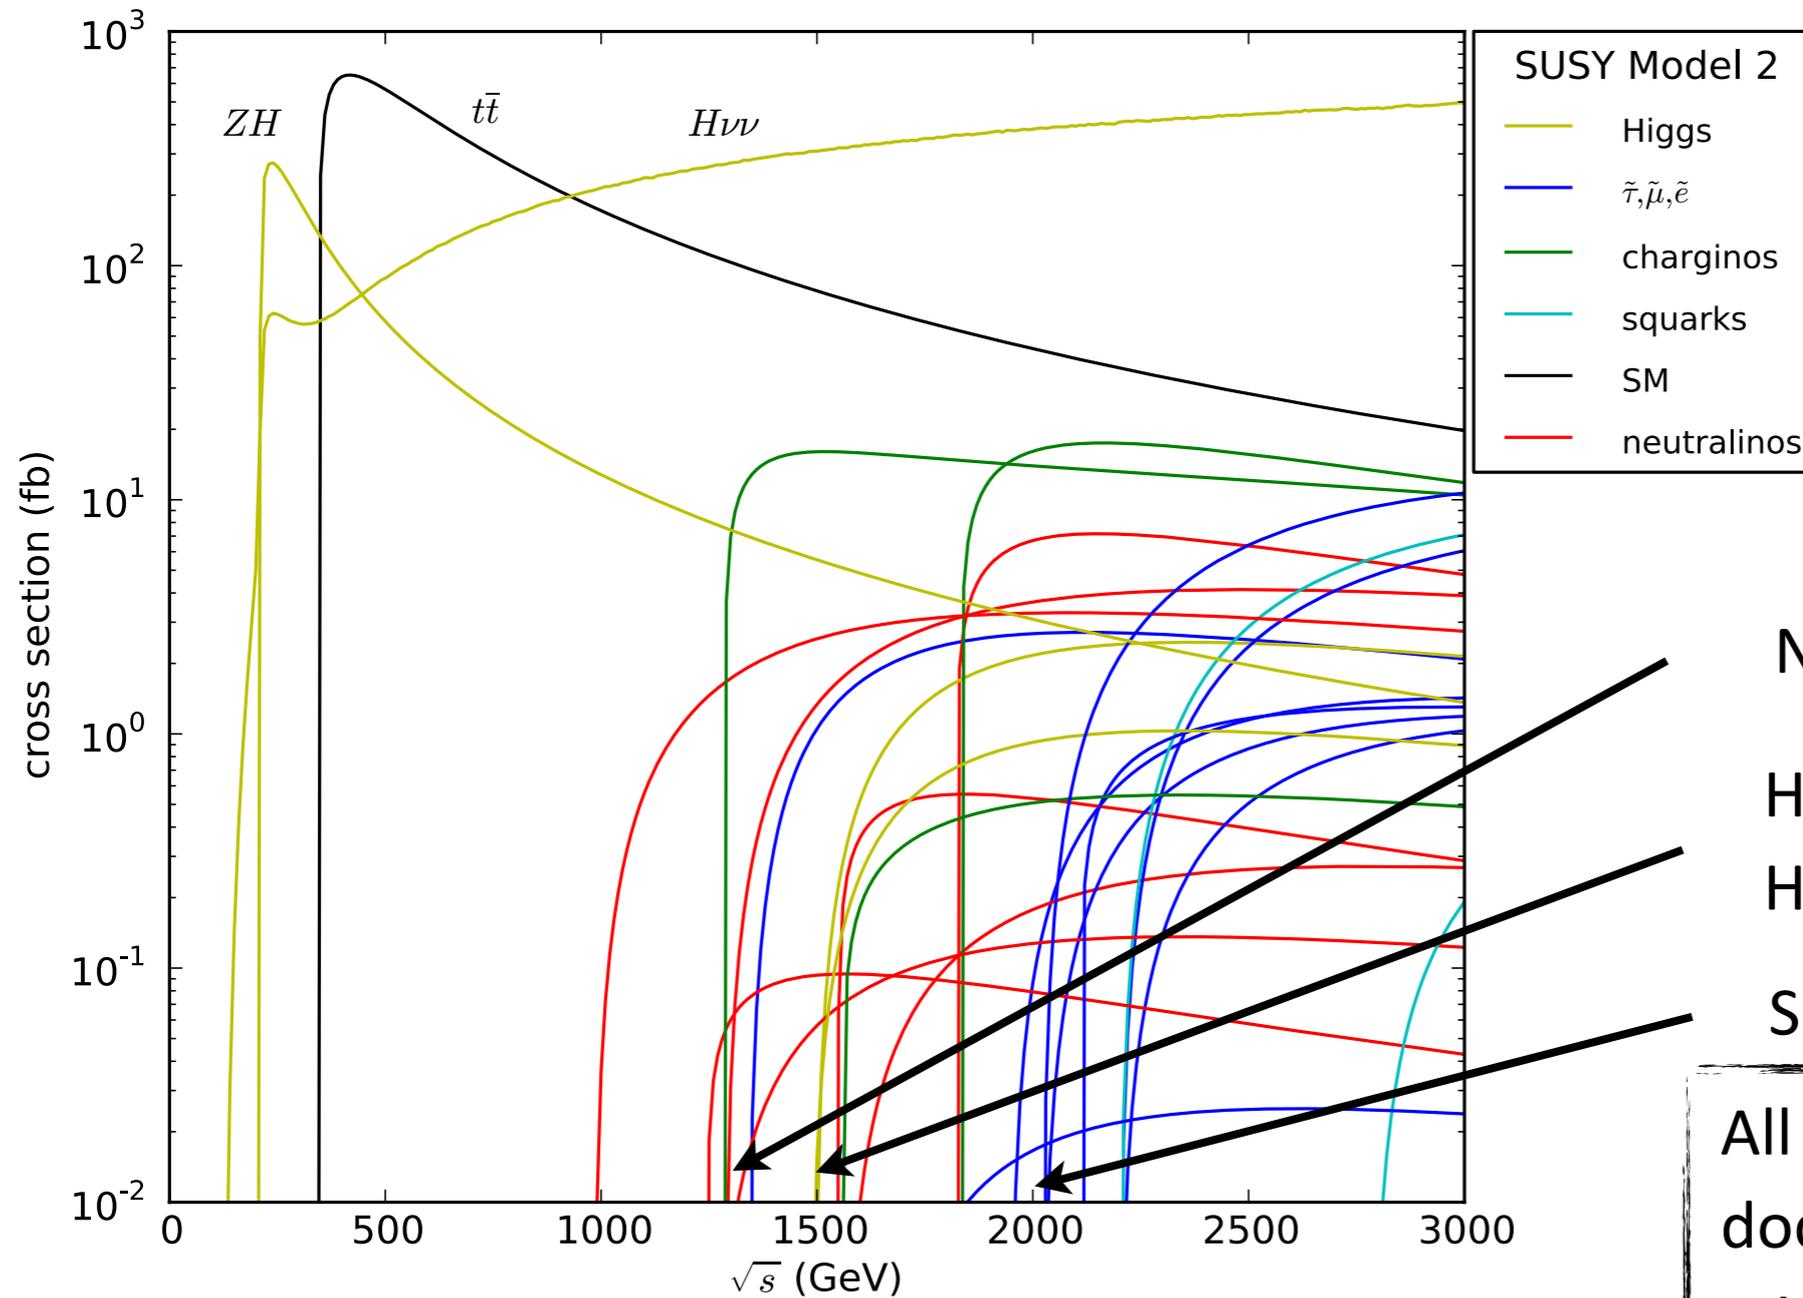

3 TeV SUSY Studies - Model I

- Two SUSY scenarios with non-unified gaugino masses - Chosen to illustrate detector performance, emphasis on high-mass states for the 3 TeV case

3 TeV SUSY Studies - Model II

- Two SUSY scenarios with non-unified gaugino masses - Chosen to illustrate detector performance, emphasis on high-mass states for the 3 TeV case

Model 2:
High mass sleptons,
Light charginos and
neutralinos dominated
by single decay mode

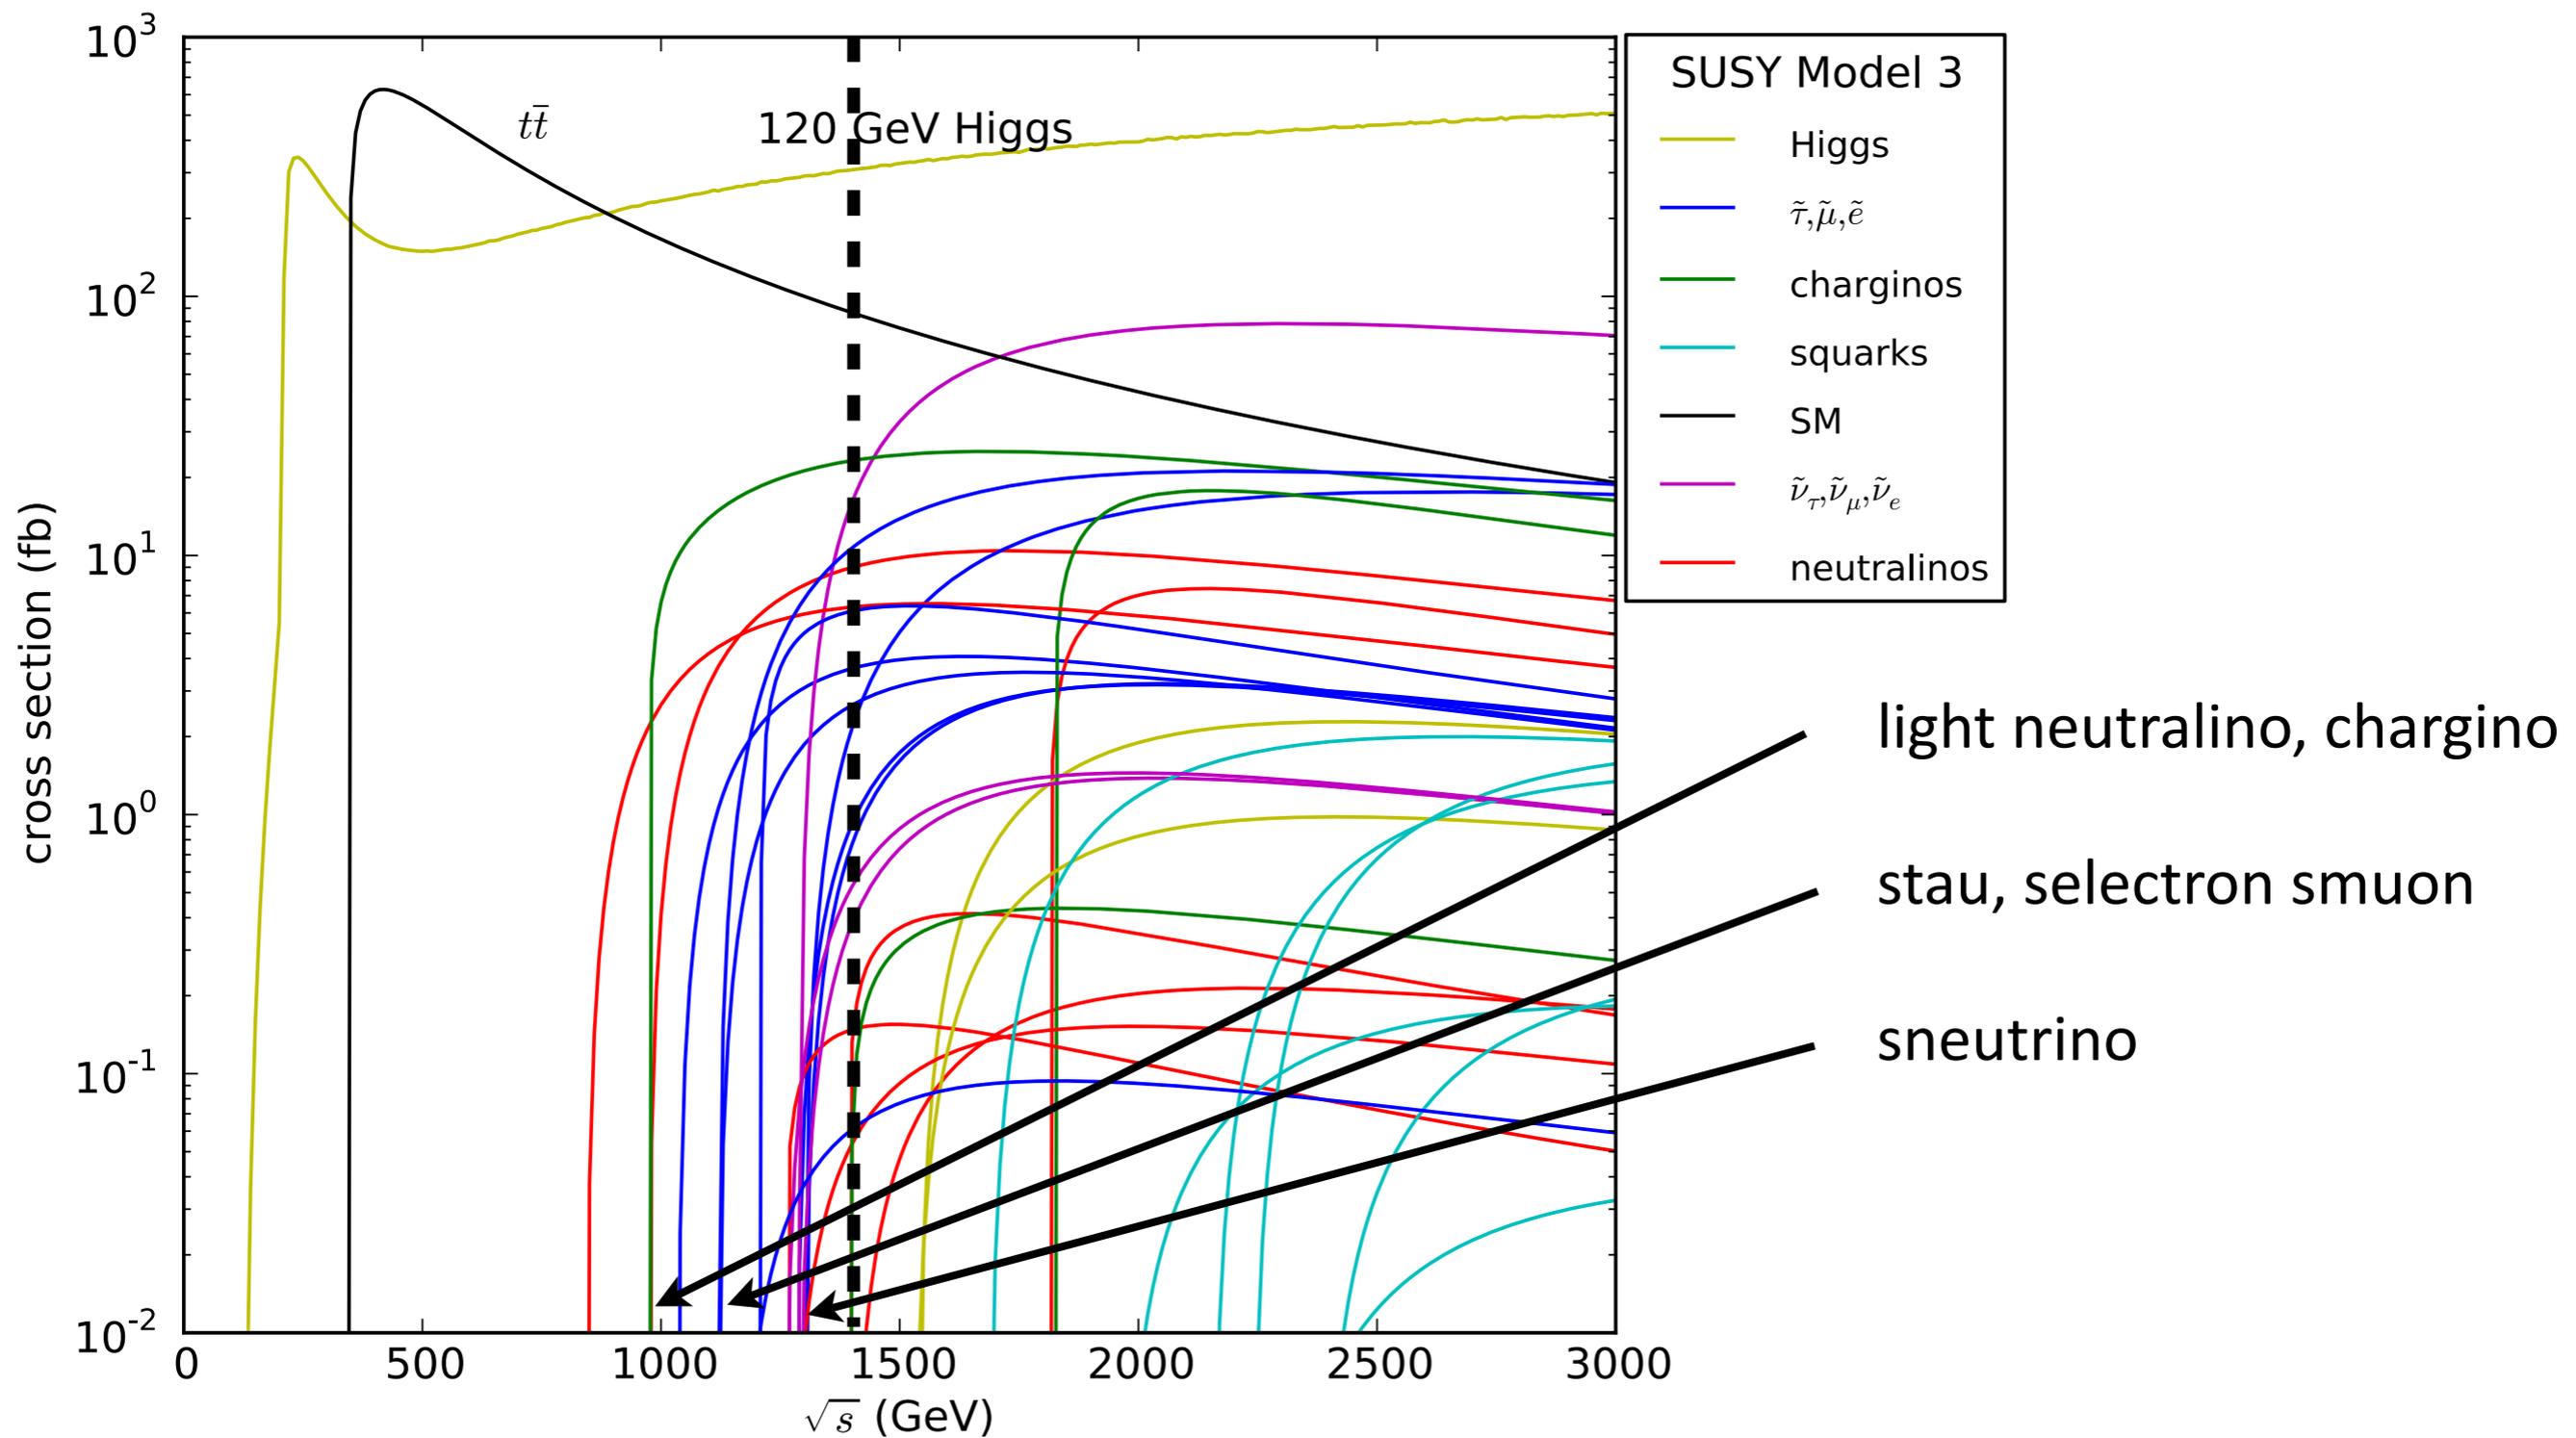

Neutralinos, Charginos

Heavy Higgs:
 $H^{+-}, H^0 A^0$

Sleptons

All studies extensively
documented in CLIC CDR vol2:
arXiv:1202.5940

1.4 TeV SUSY Studies - Model III

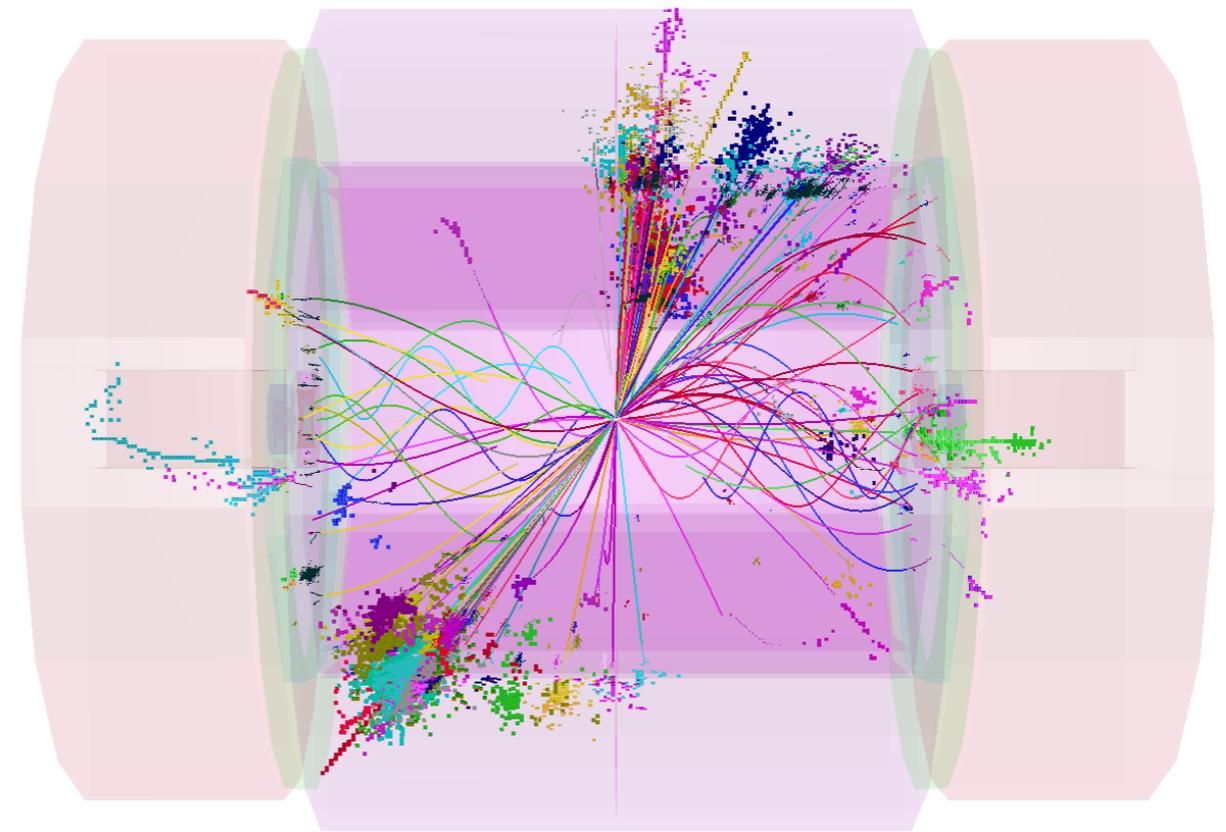

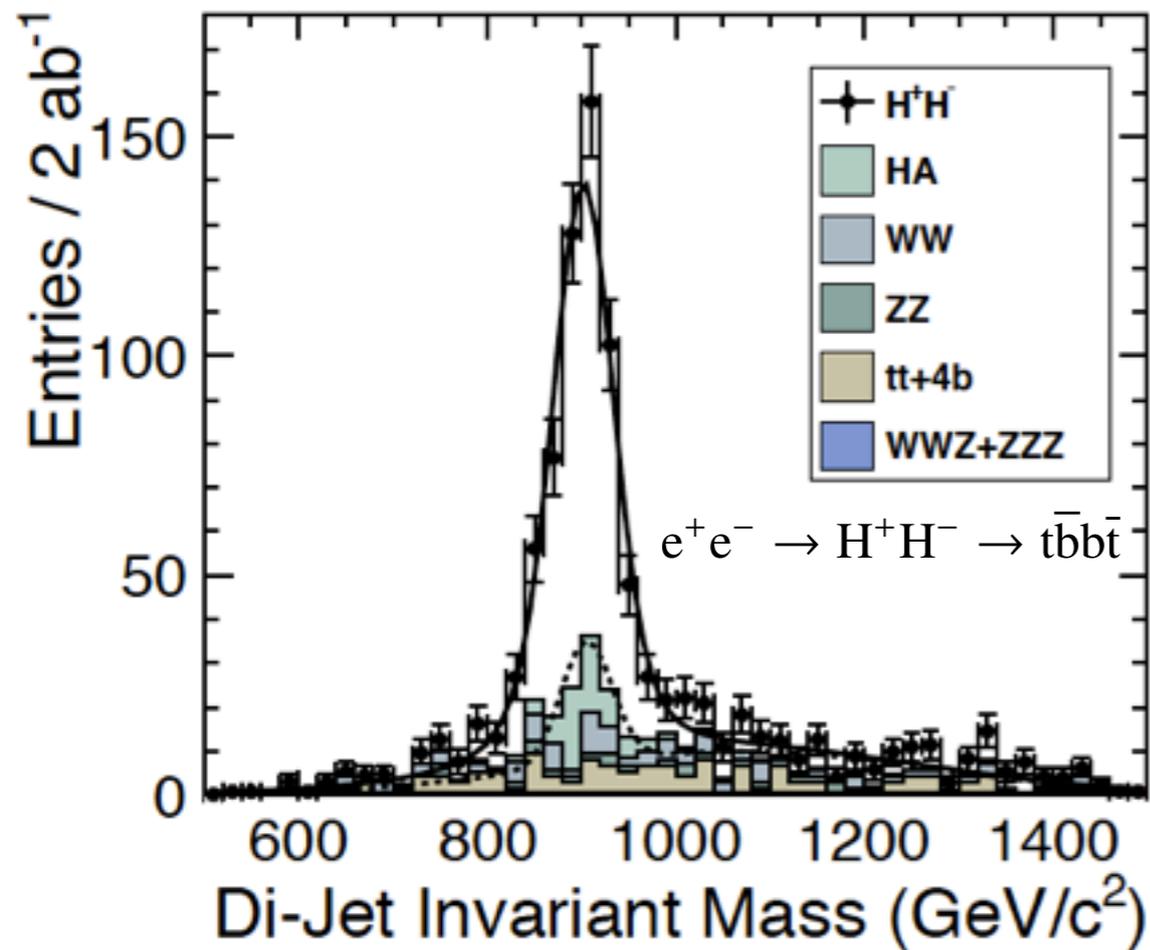

The SUSY Higgs Sector at 3 TeV

- Heavy charged and neutral Higgses:

$$e^+e^- \rightarrow H^0 A^0 \rightarrow b\bar{b}b\bar{b}$$

$$e^+e^- \rightarrow H^+ H^- \rightarrow t\bar{b}b\bar{t}$$

Model I: 905 GeV mass

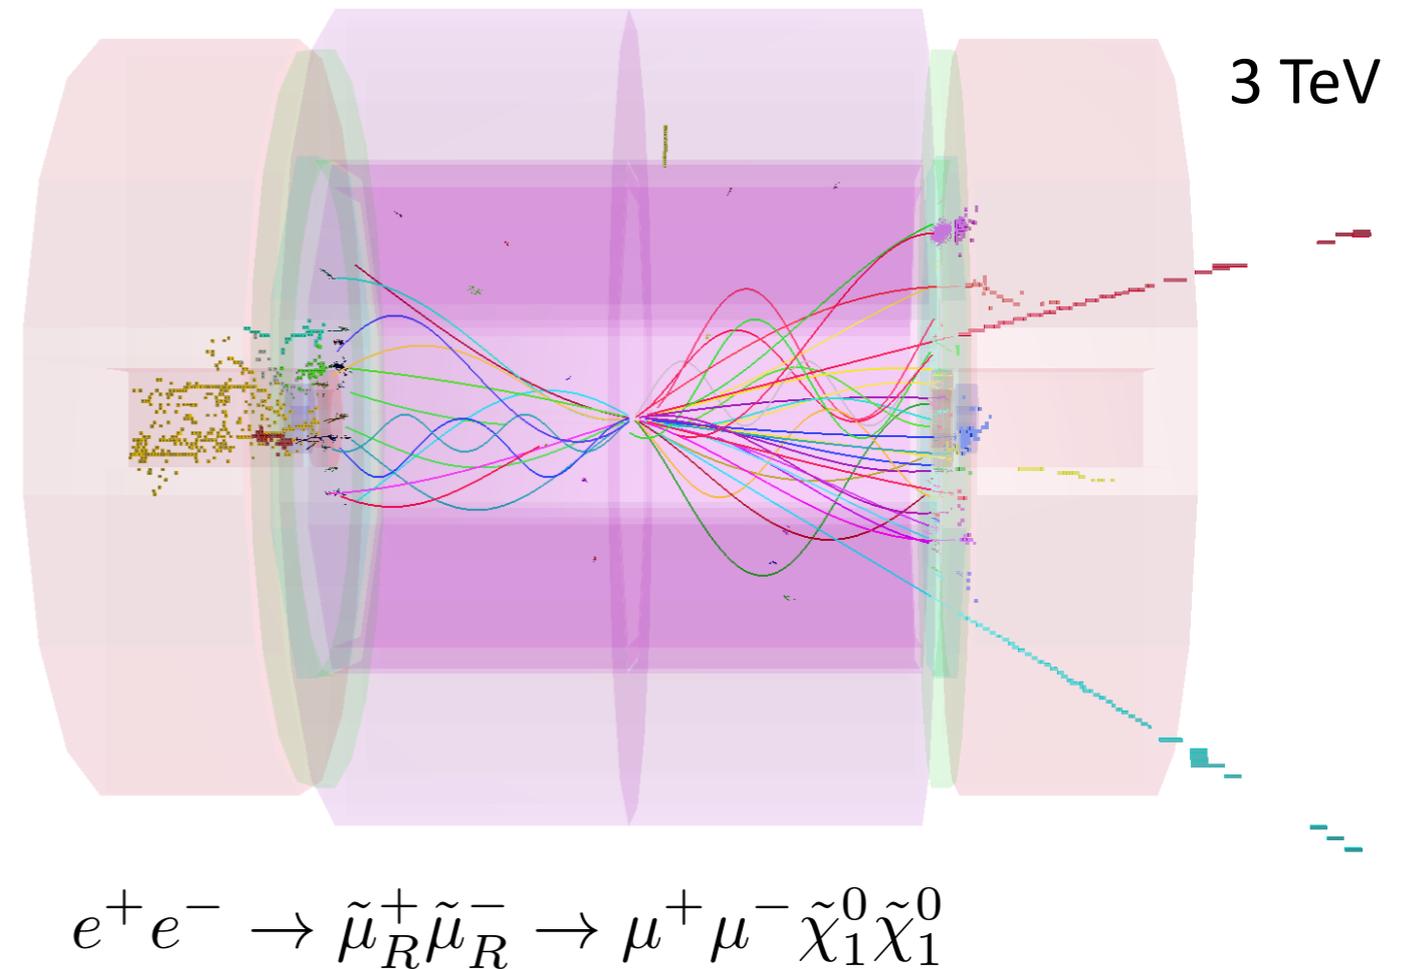

8-Jet final states, flavor tagging crucial!

- 0.3% mass resolution, 20% - 30% resolution on the width

LCD-Note-2010-006

Sleptons: Clean events

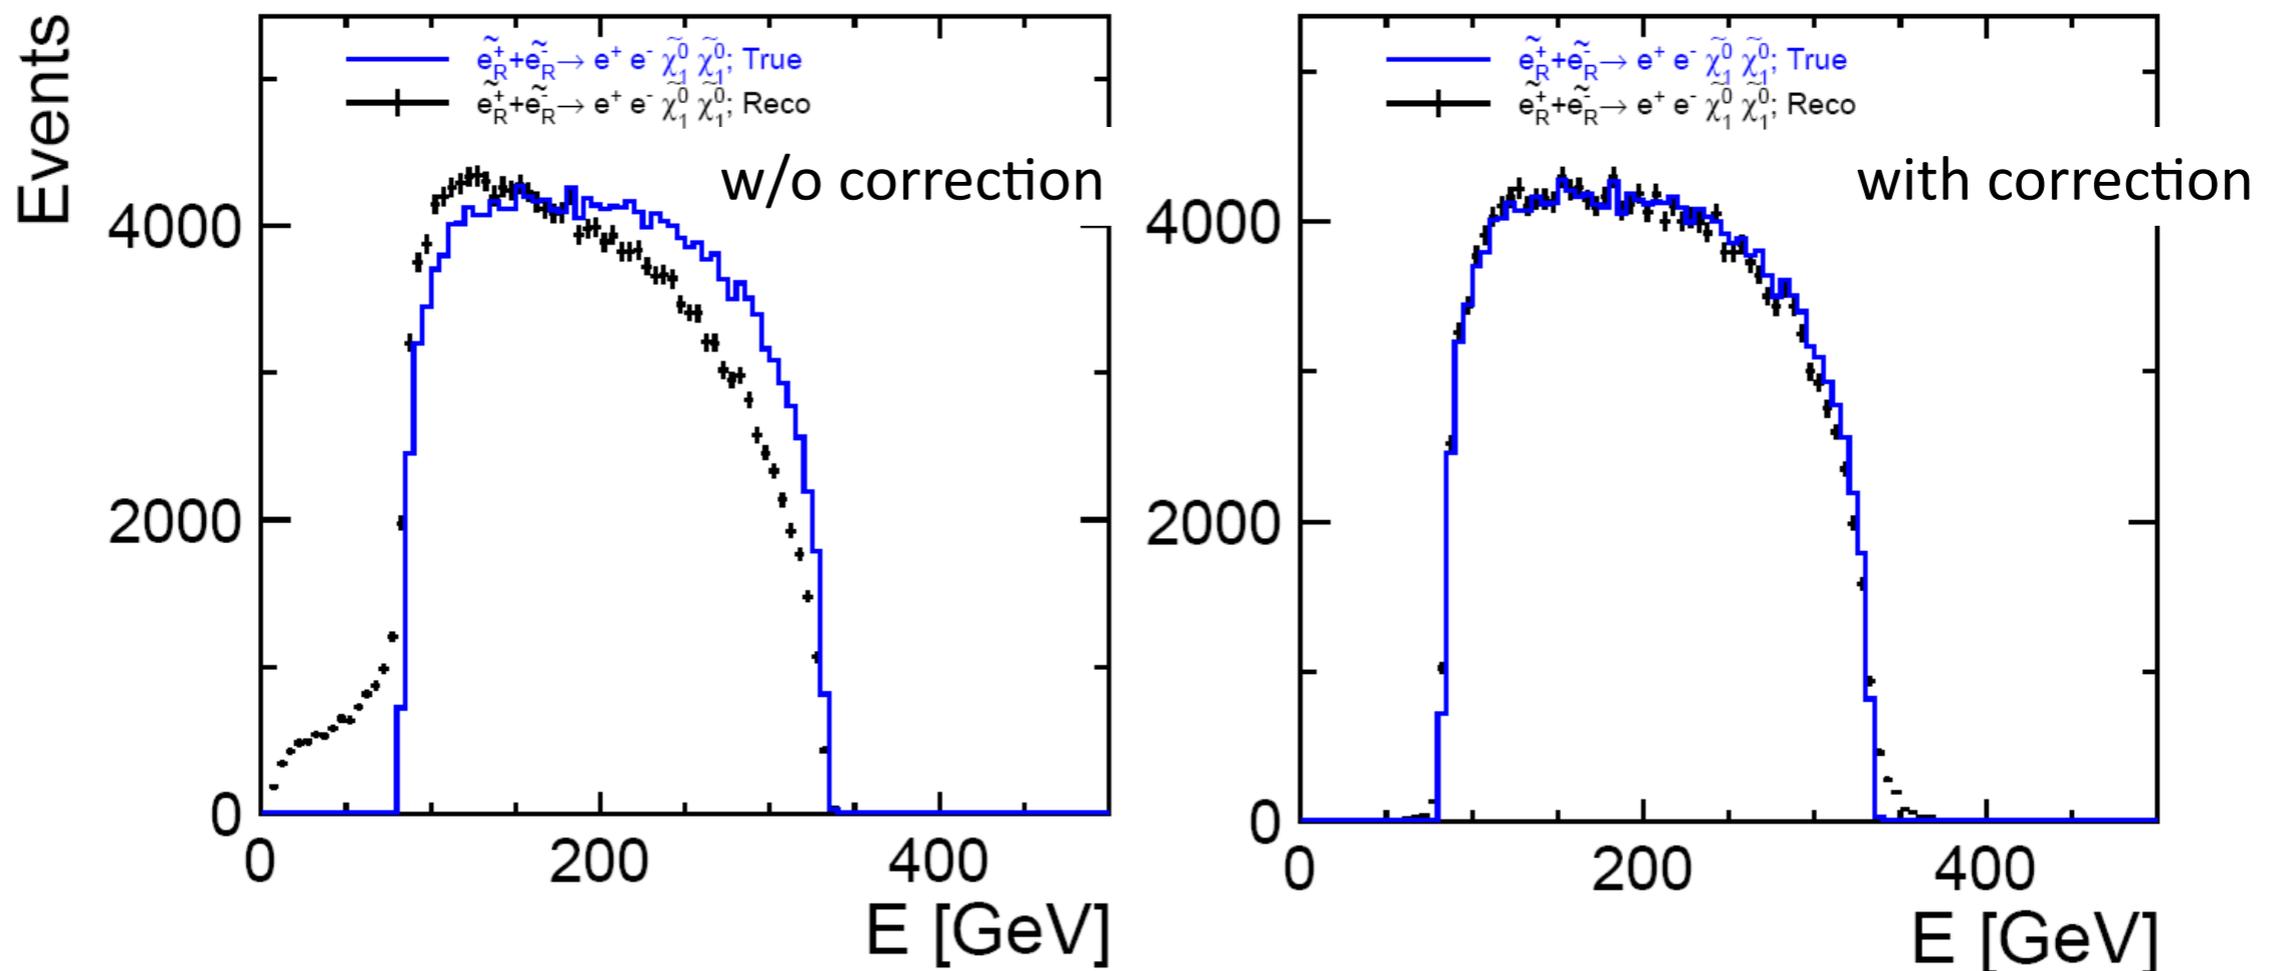

- High-energy leptons easy to identify, in particular after rejection of minijet-background
- Strategy:
 - Pre-selection cuts requiring high energy leptons inside detector acceptance with large di-lepton mass
 - Boosted Decision Tree using lepton energies, momenta, masses, acoplanarity

High selection efficiencies, 97% for di-muon and 94% for di-electron final states

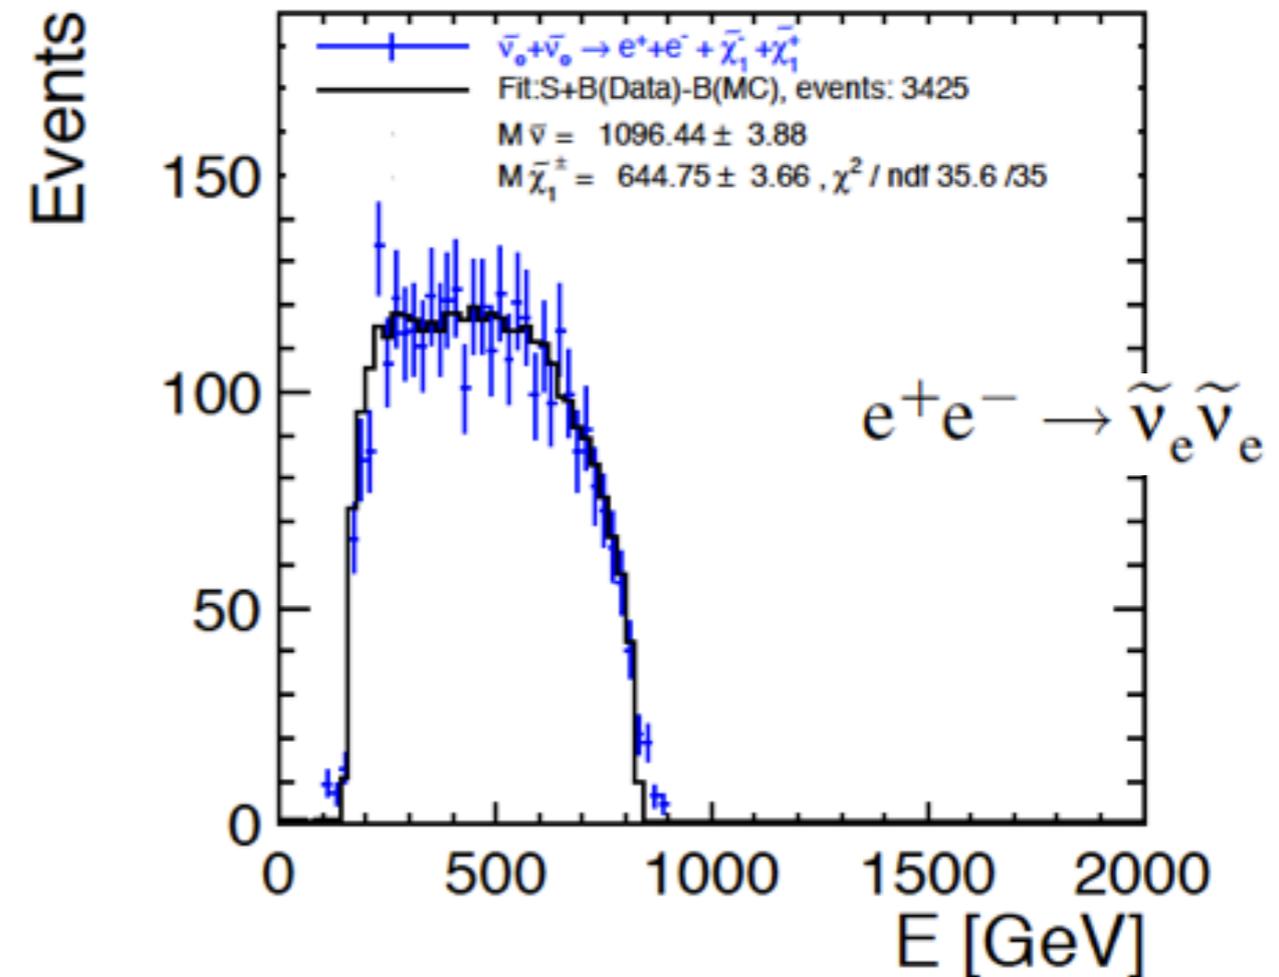

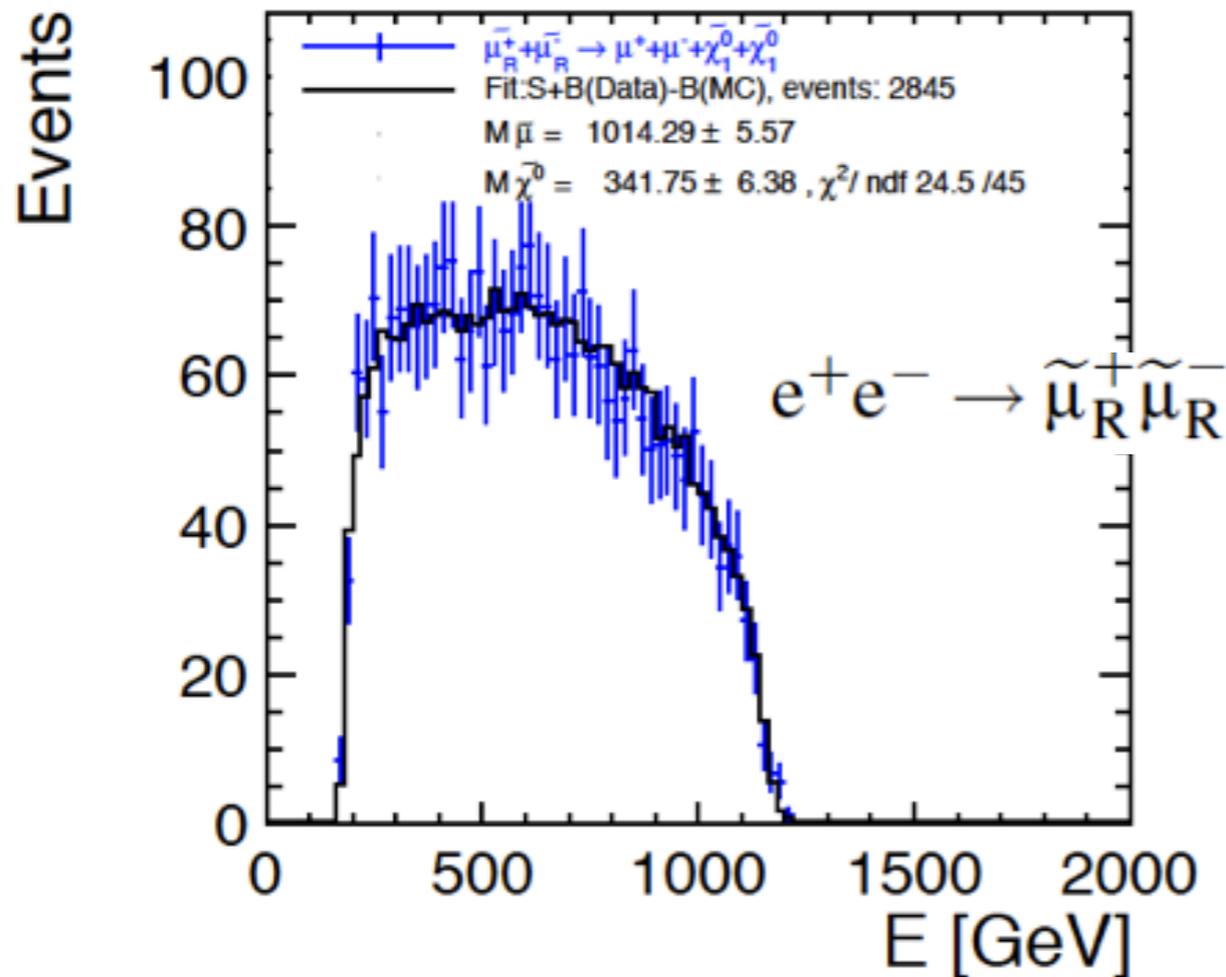

Sleptons at 1.4 and 3 TeV

- Model III selectron & smuon masses: right: 559 GeV, left: 650 GeV
- Reconstruction of two high-energy leptons
 - Quite insensitive to $\gamma\gamma \rightarrow$ hadrons background, clean samples with isolation & p_t cuts
 - Key reconstruction feature: Photon radiation correction (in particular for electrons)

Sleptons: Mass Resolution at 3 TeV

- At 3 TeV: TeV-scale sleptons

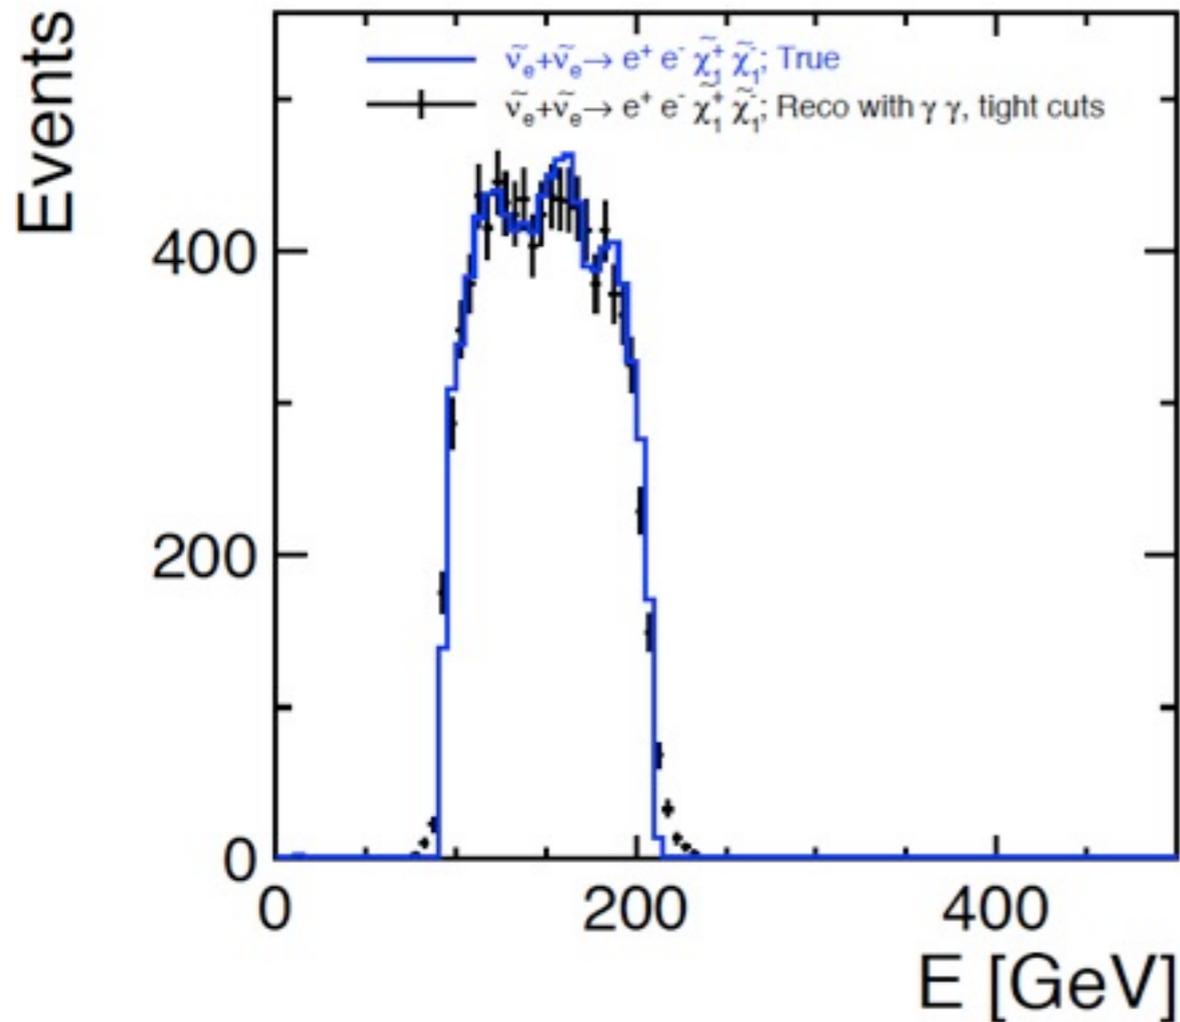

- Background rejection with multivariate techniques
- Mass fit using beam energy spectrum, simultaneous fit of slepton and gaugino mass, $\sim 0.5\%$ precision

LCD-Note-2011-018

Further Slepton Studies

- Study of staus at 1.4 TeV (stau masses 517 GeV and 642 GeV) in progress
 - Main challenge: Tau reconstruction and tau energy measurement
- Sneutrino studies also at 1.4 TeV (mass 644 GeV)
 - Challenges mainly due to low cross section - close to production threshold!

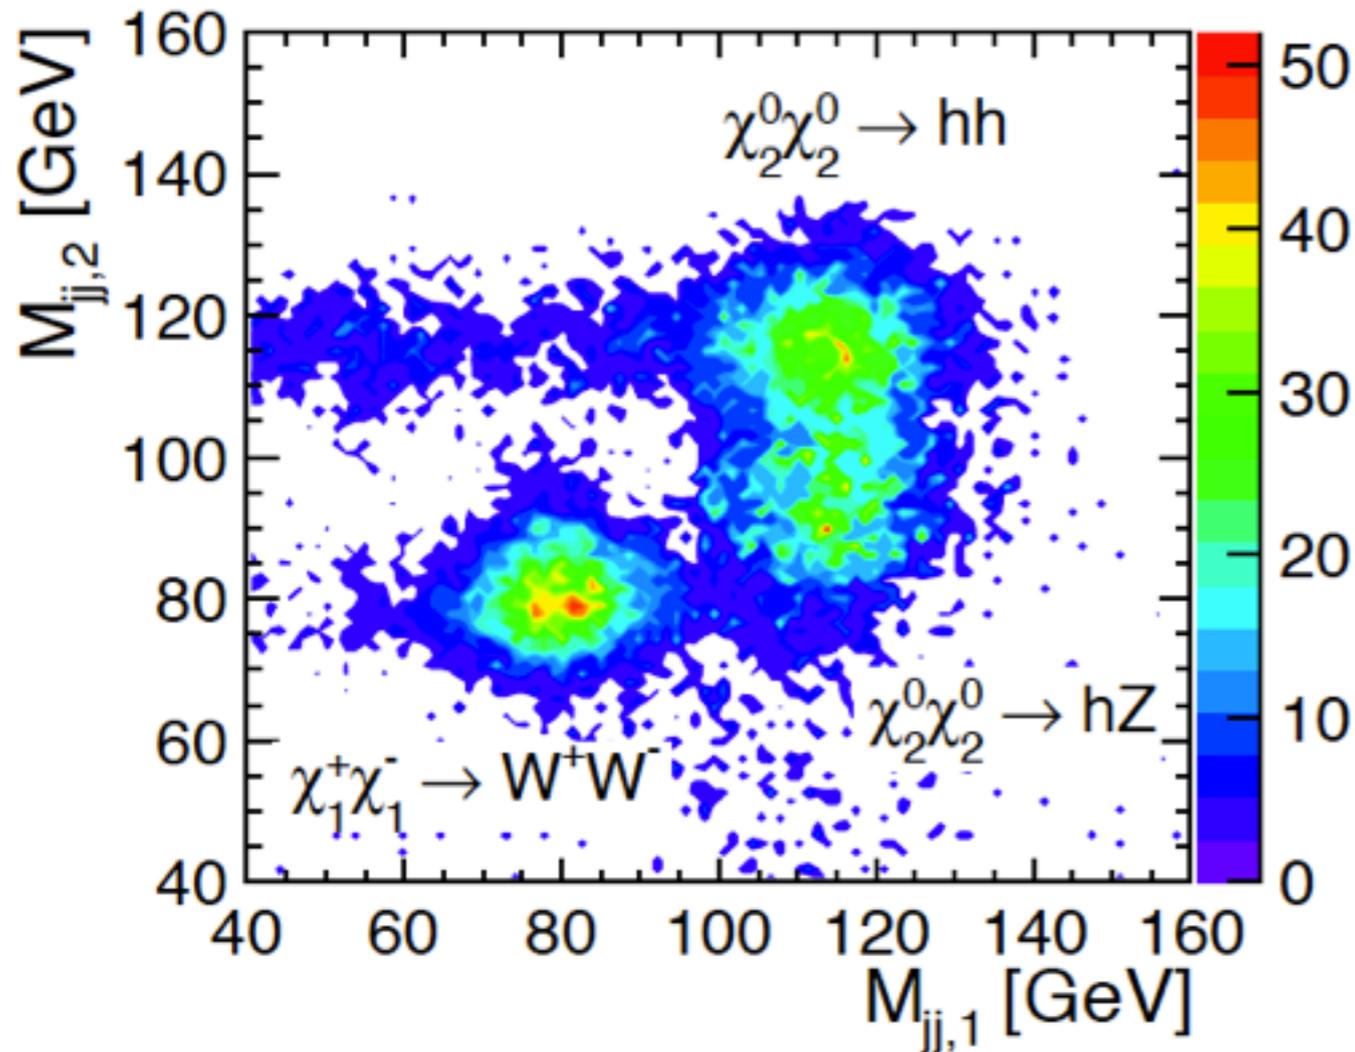

Work in progress:

Despite small cross-section, expect
~12 GeV resolution on sneutrino
and chargino mass

profiting from very low background levels in
2 leptons + 4 jets channel

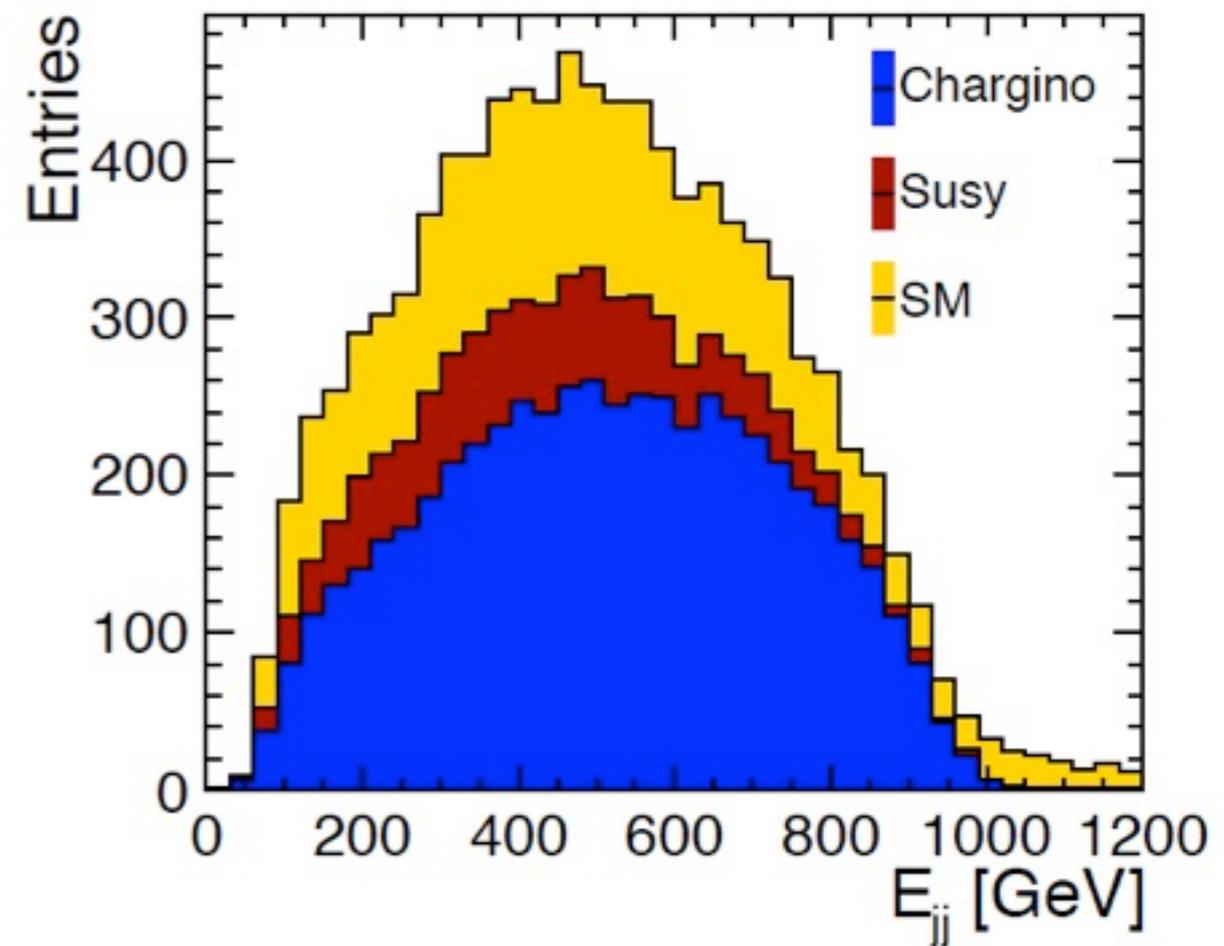

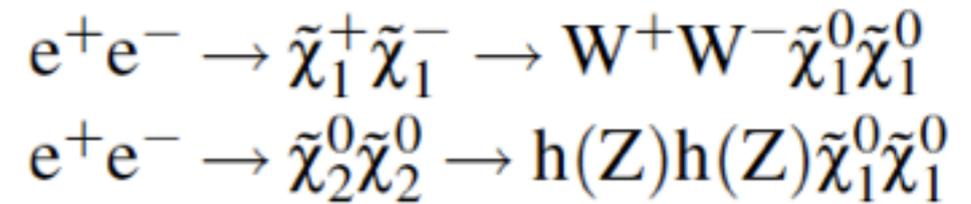

Charginos, Neutralinos at 1.4 and 3 TeV

- A perfect example for the power of PFA:
 - Multi-jet final states and missing energy

- Mass determined through template fit
Statistical precision $\sim 1\%$

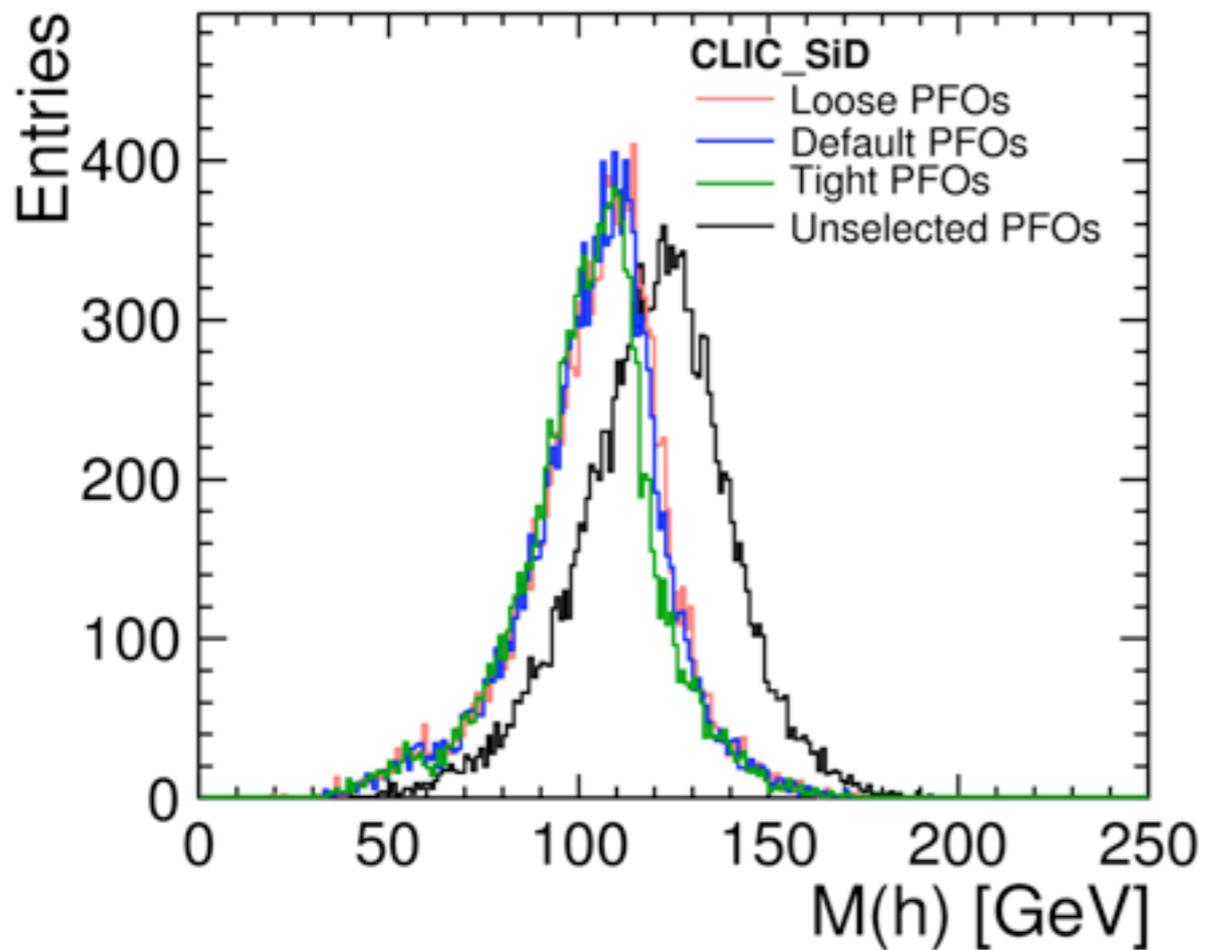

3 TeV, Neutralino & Chargino-Masses of 643 GeV

LCD-Note-2011-037

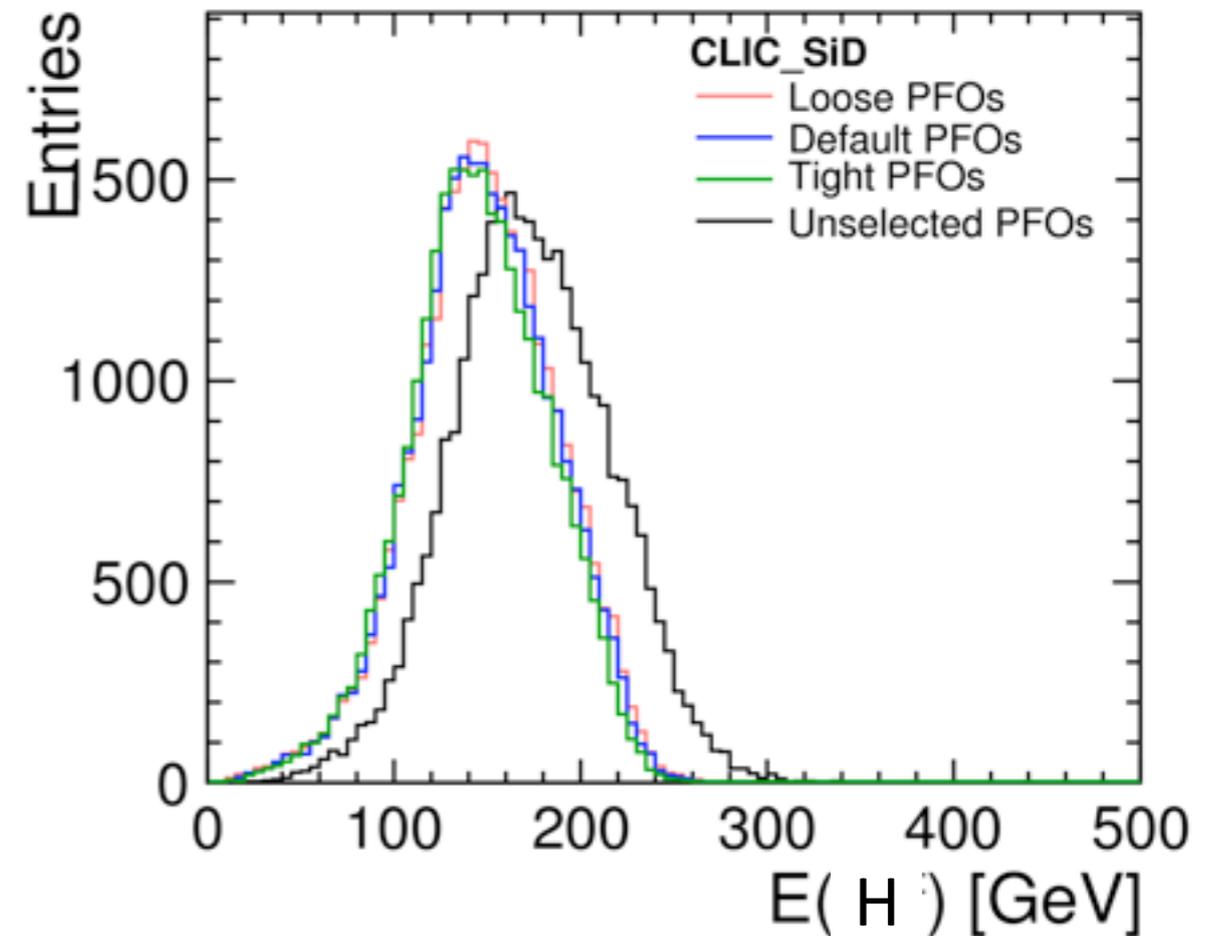

Charginos, Neutralinos at 1.4 and 3 TeV

- Charginos & Neutralinos in Model III at 1.4 TeV - Work in progress:
 - Neutralino2 decays to 95% into HX_1 , H almost at rest

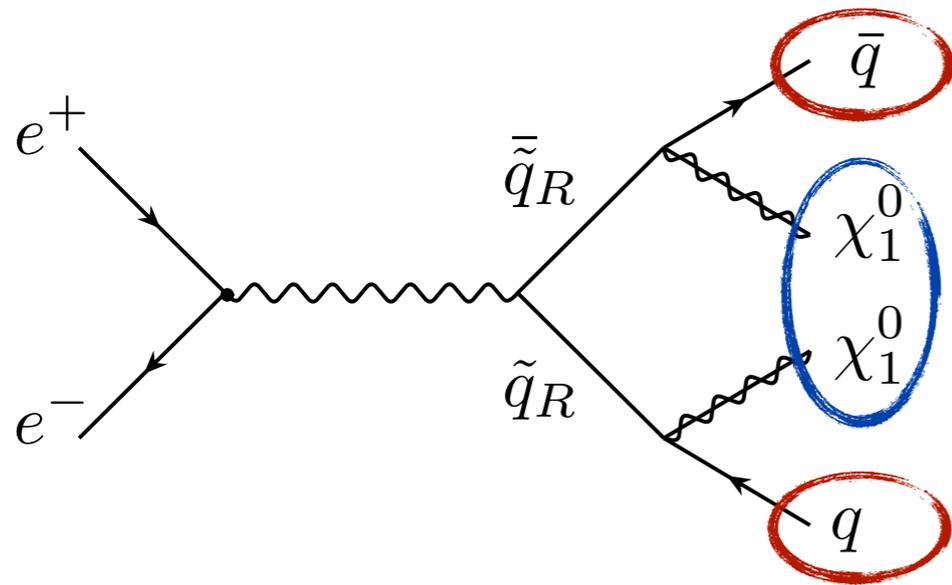

Extracting Neutralino mass from energy distribution of di-jet system

Higgs reconstruction in the presence of $\gamma\gamma \rightarrow$ hadrons background:
Timing cuts crucial!

Masses of light-flavored Squarks at 3 TeV

two highly energetic jets

missing energy

Right-Squark masses of 1.12 TeV

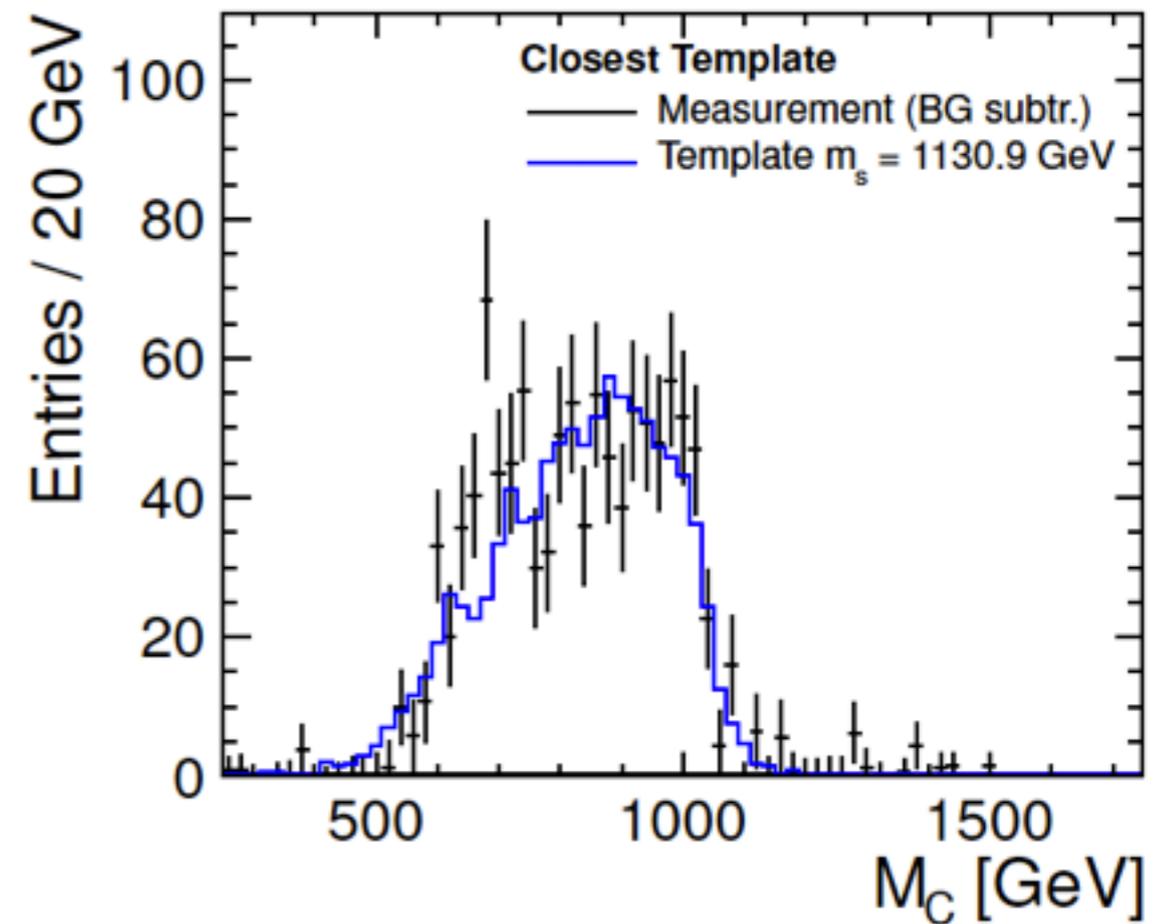

(up & down -type nearly mass degenerate)

- Mass measurement:

$$M_C = \sqrt{2(E_1 E_2 + \vec{p}_1 \cdot \vec{p}_2)}$$

Independent of s : Reduced sensitivity to luminosity spectrum, mass extraction assuming knowledge of Neutralino mass

- Mass from template fit:
0.5% statistical precision

LCD-Note-2011-027

Conclusion

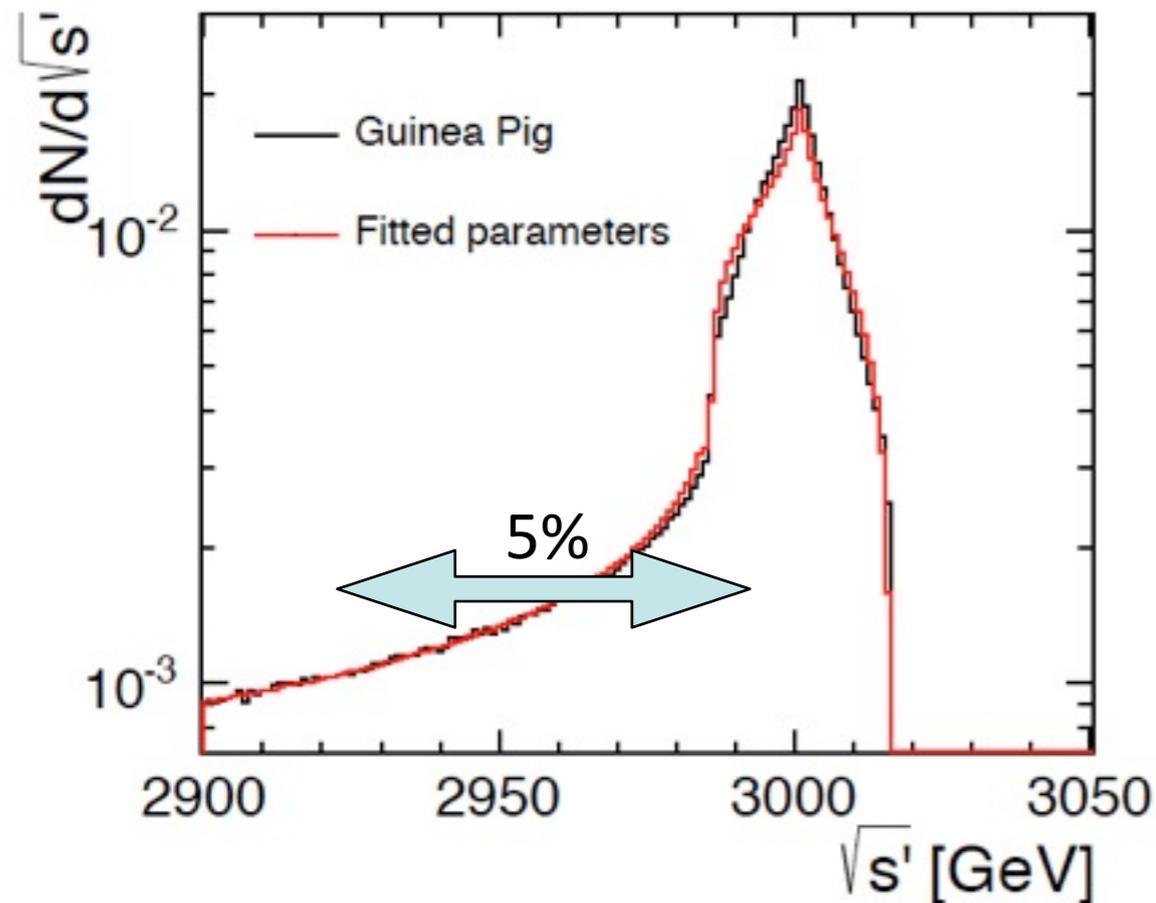

- In realistic scenarios, CLIC will be constructed in several stages:
Interesting physics at each stage!
 - Exact energies driven by physics thresholds and machine considerations
- For the CDR, we are studying a rich program:
 - Precision Standard Model physics
 - Full exploration of the Higgs
 - Top measurements
 - Supersymmetry in a variety of models: Gauginos, Sleptons, Squarks
- Full simulations including luminosity spectrum and backgrounds show that precision measurements can be done!

Backup

Systematics from Luminosity Spectrum

- The luminosity spectrum enters in most analyses: Affects edge shapes, cross section normalizations,...
- Ongoing studies to assess precision of spectrum measurement with wide-angle Bhabha scattering

- Ad-hoc study: move 5% from peak to tail and vice versa - final accuracy expected to be significantly better
- Impact:
 - Sleptons: smaller than stat. uncertainty, except X_1^0 mass: up to 1%
 - Charginos / Neutralinos: 0.5 x stat. uncertainty on mass
 - Squarks: Far below stat. uncertainty on mass due to choice of M_C (indirect sensitivity to Neutralino mass)

SUSY Model III - The Details

Neutralinos ($\tilde{N}_{1,2,3,4}$) : 357, 487, 904, 911

Charginos ($\tilde{C}_{1,2}$) : 487, 911

Sleptons ($\tilde{e}_R, \tilde{e}_L, \tilde{\nu}_e$) : 559, 650, 644

($\tilde{\tau}_1, \tilde{\tau}_2, \tilde{\nu}_\tau$) : 517, 642, 630

Squarks ($\tilde{t}_1, \tilde{t}_2, \tilde{b}_1, \tilde{b}_2$) : 844, 1120, 1078, 1191

($\tilde{d}_R, \tilde{u}_R, \tilde{d}_L, \tilde{u}_L$) : 2167, 2181, 2197, 2196

Higgs bosons (h^0, A^0, H^0, H^\pm) : 117.8, 765, 765, 769

$$\Omega_{\text{DM}} h^2 = 0.110$$

$$\sigma_{\text{SI}}(\text{nucleon}, \tilde{N}_1) = 7.4 \times 10^{-10} \text{ pb}$$

$$\Delta(g-2)_\mu = 6.35 \times 10^{-10}$$

$$\text{BR}(B_s \rightarrow \mu^+ \mu^-) = 4.0 \times 10^{-9}$$

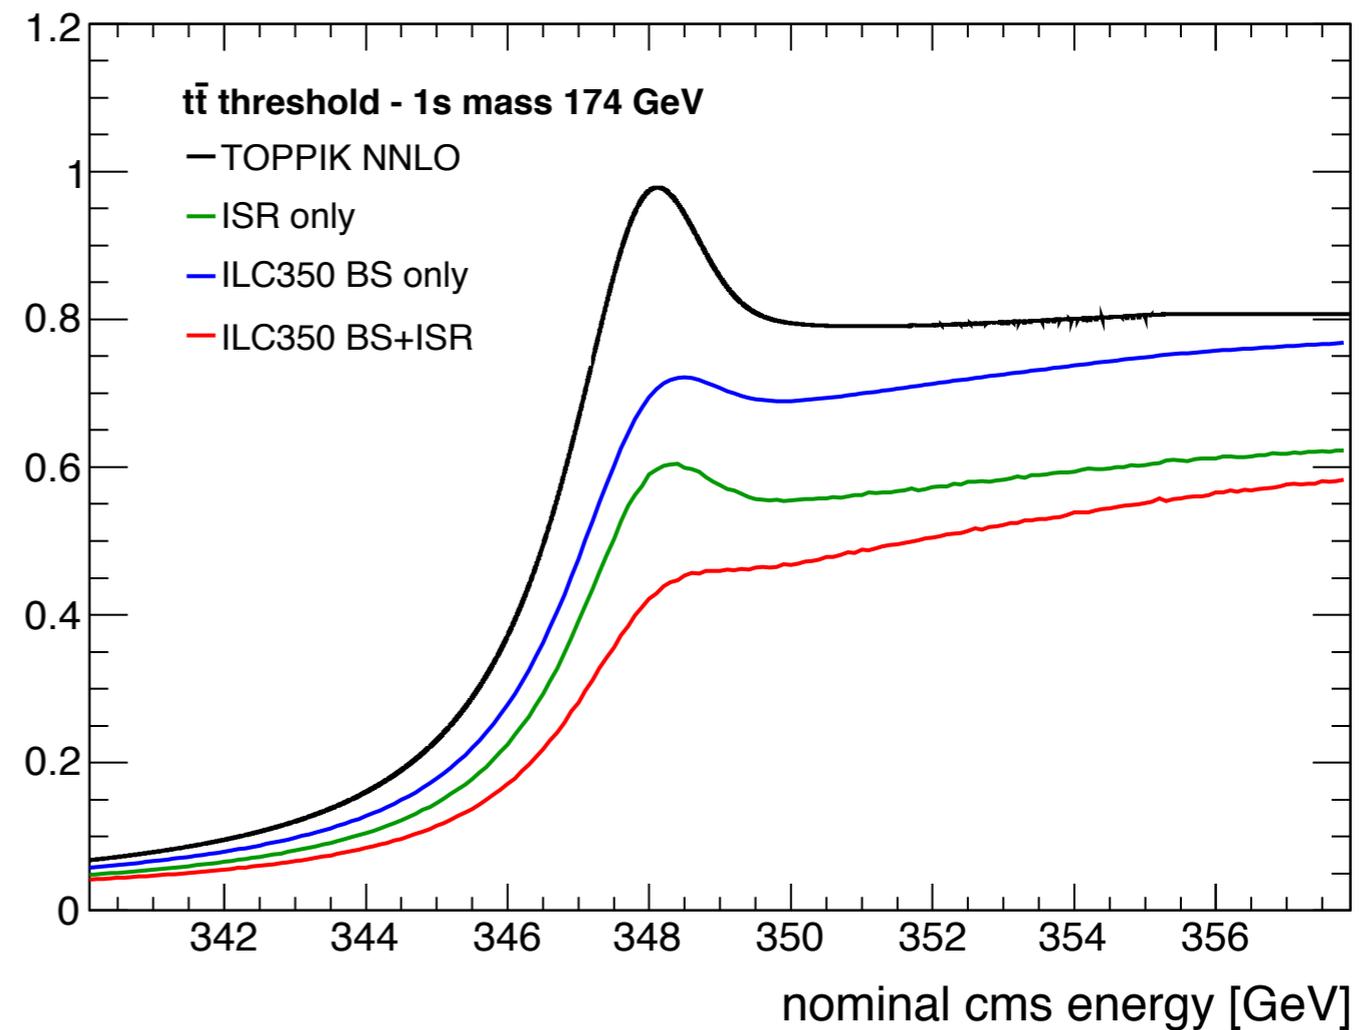

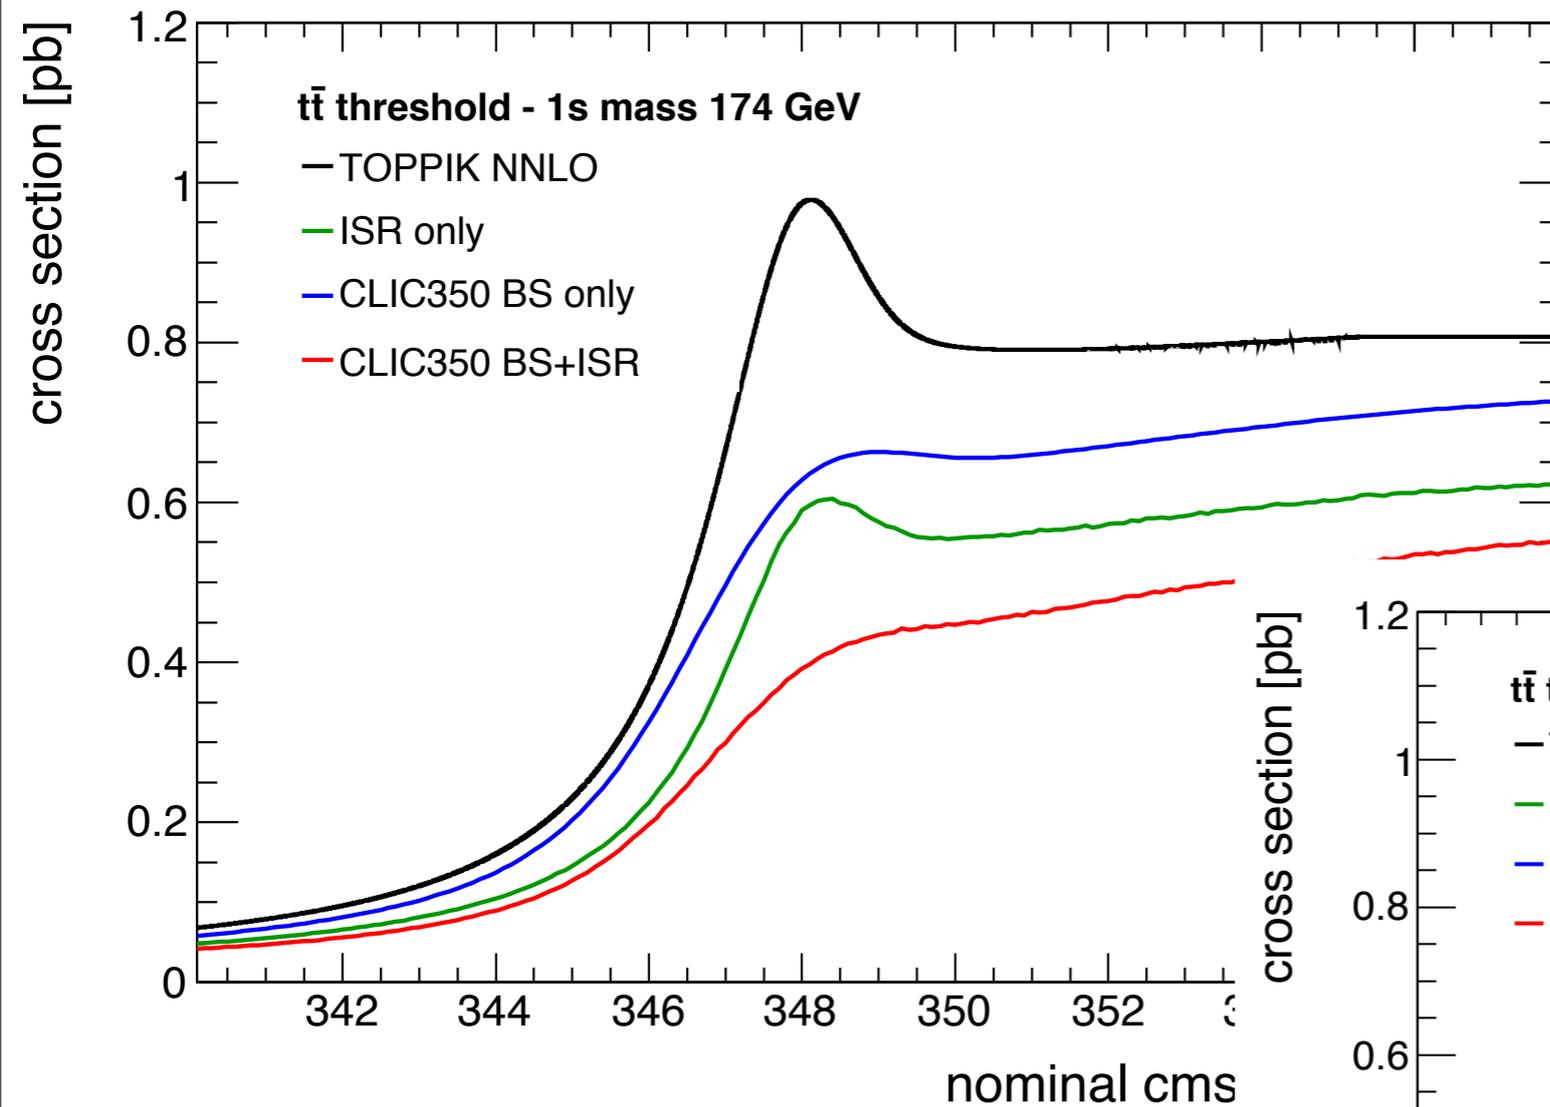

$$\text{BR}(b \rightarrow s \gamma) = 3.26 \times 10^{-4}$$

At 1.4 TeV:

Pair production of
sleptons and
gauginos

Squarks, heavy
Higgs above
threshold

Top Threshold: CLIC vs ILC

Broader beam energy spectrum leads to softening of edge: Some reduction of sensitivity, but not a show stopper!

CLIC_ILD Detector - Main Features

low-mass, high precision vertex detector:

Si pixel detector

Si strip inner tracker

ILD (500GeV): 15mm

CLIC_ILD (500GeV): 25mm

CLIC_ILD (3TeV): 31mm

Detectors concept follows the ILC designs: CLIC_ILD

forward calorimeters for luminosity measurements and overall detector hermeticity

magnet yoke with muon detector / tail catcher

precision tracking:

- SiD: Si strip main tracker
- ILD: TPC main tracker

high-field solenoid

- All detectors inside solenoid
- Magnetic field: CLIC_ILD at 4 T

highly granular calorimeters for particle flow

- Hcal: 7.5λ , steel in endcap, tungsten in barrel
