## **Problems Lecture 1: Lattice Design**

1) A transport lattice with no acceleration consists of FODO cells with quadrupole spacing L = 10 m and focal distance f = 7 m. How large is the phase advance?

2) Estimate the RMS beam jitter at a position with  $\beta(s_2) = 1 \text{ m}$  if one quadrupole jitters  $450^{\circ}$  upstream with a focal length f = 7 m and  $\beta(s_1) = 10 \text{ m}$ . The quadrupole jitter amplitude has an RMS of  $1 \mu \text{m}$ .

3) Calculate the average beta-function in a thin lens FODO lattice as a function of  $\hat{\beta}$ ,  $\check{\beta}$  and L/f

4) How much does a cavity with tilt  $\theta \ll 1$  deflect the beam?

## **Solutions**

1) We use

$$\cos \mu = 1 - \frac{L^2}{2f^2}$$
$$\Rightarrow \mu = \arccos\left(\frac{1}{2}\right) \approx 91.169^\circ$$

2) The angular deflection is given by the offset  $\delta$  and the focal strength f

$$y' = \frac{\delta}{f}$$

we transform into nromalised phase space

$$y_N' = \sqrt{\beta(s_1)} \frac{\delta}{f}$$

 $450^{\circ}$  downstream this is

$$y_N = \sqrt{\beta(s_1)} \frac{\delta}{f}$$

which translates into

$$y = \sqrt{\beta(s_1)\beta(s_2)} \frac{\delta}{f}$$

inserting number we find

$$y \approx 0.45\delta$$

hence the RMS jitter  $\sigma_{y,jitt} = 0.45 \,\mu\text{m}$ .

## **Solutions**

3) We will integrate from the centre of a defocusing quadrupole (at s = 0) to the centre of the next focusing quadrupole (at s = L). In the centre of the defocusing quadrupole we have  $\beta = \check{\beta}$  and  $\alpha = 0$ . We calculate the Twiss parameters immediately after the quadrupole (at  $\epsilon \rightarrow 0$ ):

$$\begin{pmatrix} \beta(\epsilon) & -\alpha(\epsilon) \\ -\alpha(\epsilon) & \gamma(\epsilon) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1/(2f) & 1 \end{pmatrix} \begin{pmatrix} \check{\beta} & 0 \\ 0 & 1/\check{\beta} \end{pmatrix} \begin{pmatrix} 1 & 1/(2f) \\ 0 & 1 \end{pmatrix}$$
$$\Rightarrow \begin{pmatrix} \beta(\epsilon) & -\alpha(\epsilon) \\ -\alpha(\epsilon) & \gamma(\epsilon) \end{pmatrix} = \begin{pmatrix} \check{\beta} & \check{\beta}/(2f) \\ \check{\beta}/(2f) & 1/\check{\beta} + \check{\beta}/(2f)^2 \end{pmatrix}$$

now we calculate beta along a drift using

$$\begin{pmatrix} \beta(s) & -\alpha(s) \\ -\alpha(s) & \gamma(s) \end{pmatrix} = \begin{pmatrix} 1 & s \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \check{\beta} & \check{\beta}/(2f) \\ \check{\beta}/(2f) & 1/\check{\beta} + \check{\beta}/(2f)^2 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ s & 1 \end{pmatrix}$$
$$\beta(s) = \check{\beta} + \frac{\check{\beta}}{f}s + \left(\frac{1}{\check{\beta}} + \frac{\check{\beta}}{4f^2}\right)s^2$$
$$\langle \beta \rangle = \frac{1}{L} \int_0^L \beta(s) ds = \check{\beta} + \frac{\check{\beta}}{2f}L + \frac{L^2}{3} \left(\frac{1}{\check{\beta}} + \frac{\check{\beta}}{4f^2}\right)$$

to avoid to much calculation we exploit

$$\beta(L) = \hat{\beta} = \check{\beta} + \frac{\check{\beta}}{f}L + \left(\frac{1}{\check{\beta}} + \frac{\check{\beta}}{4f^2}\right)L^2$$

hence

$$\left<\beta\right> = \frac{2}{3}\check{\beta} + \frac{1}{3}\hat{\beta} + \frac{L}{6f}\check{\beta}$$

## **Solutions**

4) The deflection of the beam by a single structure of length *L* and gradient *G* with tilt  $\theta \ll 1$  is

$$\delta y' = \frac{eGL}{2}\frac{1}{E}\theta = \frac{\delta}{2}\theta$$

 $\delta$  is the relative acceleration by the cavity.

To calculate this we have to add three contributions:

The kick applied by the central part of the structure is

$$\delta y_c' = \frac{eGL}{E}\theta = \delta\theta$$

The field at the entrance give a thin lens kick, since the particle has an offset with respect to the axis of the structure of  $y = L/2\theta$ 

$$\delta y_1' = -\frac{eGL}{2E2}\theta = -\frac{1}{4}\delta\theta$$

The offset at the exit is  $y = -L/2\theta$ , hence

$$\delta y_2' = \frac{eG}{2E} \frac{-L}{2}\theta = -\frac{1}{4}\delta\theta$$

So in total

$$\delta y' = \delta'_c + \delta'_1 + \delta'_2 = \frac{\delta}{2}\theta$$
