SUSY precission studies

LCWS, Nov 2013 1 / 29

< ロ > < 同 > < 回 > < 回 >

#### Outline

- 2 SUSY, as an experimentalist sees it
- 3 SUSY Observables

#### 4 A bench-mark point

- $\tilde{\tau}$  channels
- Channels with µ:s

4 3 > 4 3

What does SUSY look like experimentally ? What are the problems to face ?

Generically:

- $e^+e^- \rightarrow \tilde{X}\bar{\tilde{X}} \rightarrow X\bar{X}\tilde{Y}\bar{\tilde{Y}}$
- $\tilde{Y}$  might be stable, or further decay,  $\tilde{Y} \rightarrow Y \tilde{U}$ .
- Finally, one ends up with SM particles, and a lightest SUSY particle, the LSP.
- If R-parity (RP) is conserved, the LSP is stable. From cosmology and cosmic rays, this particle must be neutral and un-coloured.
- Ie.: Experimentally, it's like a heavy "neutrino".

- Ie.: Experimentally, it's like a heavy "neutrino".

#### Therefore:

- Conserved RP : Missing energy from the LSP, particle id of the SM products.
- Violated RP (RPV) : LSP *can* be charged and/or coloured, as the cosmological arguments evaporates. Odd signatures either a log-lived LSP, or an LSP that decays in the detector. *Won't talk about this.*

#### Furthermore:

- Amount of missing energy very important.
- Depends on the mass-difference between the last SUSY particle in the chain and the LSP.
- There is always an NLSP (Next to Lightest SUSY Particle), which is special:
  - It can only decay to it's SM-partner and the LSP.

#### So, what we look for and like to measure is:

- NLSP pairs ⇔ Missing energy and momentum + pairs of the SM partner (τ̃<sub>1</sub> gives τ, ẽ gives e, τ̃ gives t gives jet, ...)
  - Note:
    - Amount of missing stuff might spen a work reger Eq. small mass-difference between heavy sparticles gives large missing E, but a little missing p.
      - In M. Silvie a basico, SM partner is a IV(3, possibly iso of shall. At small mass differences, the set of SM particles might be non-obvious.
- Cascade decays: Still Missing energy and momentum, but id of SM particles can be mixed.

< ロ > < 同 > < 回 > < 回 >

So, what we look for and like to measure is:

- NLSP pairs ⇔ Missing energy and momentum + pairs of the SM partner (τ̃<sub>1</sub> gives τ, ẽ gives e, t̃ gives t gives jet, ...)
  - Note:
    - Amount of missing stuff might span a wide range. Eg. small mass-difference between heavy sparticles gives large missing E, but little missing p.
    - If NLSP is a bosino, SM partner is a IVB, possibly far off-shell. At small mass differences, the set of SM particles might be non-obvious.
- Cascade decays: Still Missing energy and momentum, but id of SM particles can be mixed.

## **Bosino signatures**

Depending on order of  $\mu$ ,  $M_1$ , and  $M_2$ , and on GUT-scale U(1) $\otimes$ SU(2) mass-unification:

- $\mu << M_1, M_2$ :
  - LSP and NLSP both higgsino, very low ΔM.
- *M*<sub>2</sub> < *M*<sub>1</sub> <<  $\mu$ :
  - LSP Wino, NLSP is  $\tilde{\chi}_1^{\pm},$  and is close.
- $M_1 < M_2 << \mu$ :
- If GUT  $M_1 M_2$  relation,  $\Delta M < M_{LSP}$ .

< 17 ▶

#### Background from SM:

• Real missing energy + pair of SM-particles = di-boson production, with neutrinos:

- $WW \rightarrow \ell \nu \ell \nu$
- $ZZ \rightarrow f\bar{f}\nu\nu$
- Fake missing energy + pair of SM-particles =  $\gamma\gamma$  processes, ISR, single IVB.
  - $e^+e^- \rightarrow e^+e^-\gamma\gamma \rightarrow e^+e^-f\bar{f}$ , with both  $e^+e^-$  un-detected.
  - $e^+e^- \rightarrow e^+e^- \rightarrow ff\gamma$ , with  $\gamma$  un-detected.

So, suppose we have observed SUSY. What kind of numbers can we extract from the data ?

- Two-body decays: spectra w/ end-points
  - Function of the masses and E<sub>CMS</sub>.
- Cross-section in continuum
  - Function of mass of produced sparticle, it's mixing, and of E<sub>CMS</sub> and beam polarisation.
- Angular distribution of seen stuff
  - Function of sparticle spin, mass, s vs. t-channel and E<sub>CMS</sub>.
- Cross-section with threshold scan
  - Function of mass of produced sparticle.
- Branching ratios
  - Nature of sparticles.
- Differential cross-section
  - Scalar vs fermion vs t-channel.

SUSY Observables

#### Observables: Pair-production, two-body decay

The spectrum of  $E'_{Y}$  has end-points the rectangular distribution  $E_{Y} \in \left[\frac{E_{Beam}}{2}\left(1 - (M_{U}/M_{X})^{2}\right)(1-\beta), \frac{E_{Beam}}{2}\left(1 - (M_{U}/M_{X})^{2}\right)(1+\beta)\right].$  $\beta = \sqrt{1 - \left(\frac{M_{X}}{E_{Beam}}\right)^{2}}$ 

If Y is a sfremion or a neutralino, in addition the spectrum is flat between the end-points. Then:

- Average is  $\frac{E_{Beam}}{2} \left(1 \left(M_U/M_X\right)^2\right)$ ,
- the width is  $E_{Beam} \left(1 \left(M_U/M_X\right)^2\right) \beta$ ;
- the standard deviation is the width divided by  $\sqrt{12}$ .

SUSY Observables

#### Observables: Pair-production, two-body decay

Mikael Berggren (DESY)

## Observables: Pair-production, two-body decay

- So, there are two SUSY parameters, and two independent observables in the spectrum.
- Any pair of observables can be chosen, edges, average, standard deviation, width, ...
- Which choice is the best depends on the situation.
- Just a bit of algebra to extract the two SUSY masses.
- Note that if *E<sub>beam</sub>* >> *M<sub>X</sub>*, there is just one observable (low edge becomes 0, width becomes average/2), so one should not operate too far above threshold !
- Note that there are two decays in each event: two measurements per event.
- Also note that there are not enough measurements to make a constrained fit, even assuming that the two SUSY particles in the two decays are the same: (2 × 4 unknown components of 4-momentum (=8)) ( total E and p conservation (=4) + 2 equal-mass constraints) = 2 remaining unknown (=4, +2, +2) = -0

## Observables: Pair-production, two-body decay

However:

- If the masses are known from other measurements, there are enough constraints.
- Then the events can be completely reconstructed ...
- ... and the angular distributions both in production and decay can be measured.
- From this the spins can be determined, which is essential to determine that what we are seeing is SUSY.

Furthermore:

- Looking at more complicated decays, such as cascade decays, there are enough constraints if some (but not all) masses are known.
- Allows to reconstruct eg. the slepton mass in \$\tilde{\chi}\_2^0 → \tilde{l} \eta → \eta \eta \tilde{\chi}\_1^0\$ if chargino and LSP masses are known.
- Order-of-magnitude better mass resolution.

#### But this is not all !

- The cross-section in e<sup>+</sup>e<sup>-</sup> →XX close to threshold depends both on coupling, spin and kinematics (= β).
- The distribution of the angle between the two SM-particles depends on β, in a complicated, but calculable way.
- The cross-section is different for L and R SUSY particles.
- So checking how much the cross-section changes when switching beam-polarisations measures mixing.
- Measure the helicity of the SM particle → properties of the particles in the decay, ie. in addition to the produced X, also the invisible U. In one case this is possible: In τ̃ → τχ̃<sub>1</sub><sup>0</sup> → Xν<sub>τ</sub>χ̃<sub>1</sub><sup>0</sup>.

## Example: SPS1a'/STC4

(See also D. Krücker's talk on Tuesday)

#### STC4-8

- 11 parameters.
- Separate gluino
- Higgs, un-coloured, and coloured scalar parameters separate

Parameters chosen to deliver all constraints (LHC, LEP, cosmology, low energy).

At  $E_{CMS}$  = 500 GeV:

- All sleptons available.
- No squarks.
- Lighter bosinos, up to  $\tilde{\chi}^0_3$  (in  $e^+e^- \rightarrow \tilde{\chi}^0_1 \tilde{\chi}^0_3$ )

(For STC4-8, see H. Baer, J. List, arXiv:1307:0782. For SPS1a', see J. List, P. Bechtle, P. Schade, M.B., PRD 82,no5 (2010), arXiv:0908.0876)

## Extracting the $\tilde{\tau}$ properties

See Phys.Rev.D82:055016,2010

Use polarisation (0.8,-0.22) to reduce bosino background.

From decay kinematics:

- $M_{\tilde{\tau}}$  from  $M_{\tilde{\chi}_{\tau}^0}$  and end-point of spectrum =  $E_{\tau,max}$ .
- Other end-point hidden in γγ background:Must get M<sub>χ̃1</sub> from other sources. (μ̃, ẽ, ...)

From cross-section:

• 
$$\sigma_{\tilde{\tau}} = A(\theta_{\tilde{\tau}}, \mathcal{P}_{beam}) \times \beta^3/s$$
, so  
•  $M_{\tilde{\tau}} = E_{beam} \sqrt{1 - (\sigma s/A)^{2/3}}$ : no  $M_{\tilde{\chi}_1^0}$ !

From decay spectra:

•  $\mathcal{P}_{\tau}$  from exclusive decay-mode(s): handle on mixing angles  $\theta_{\widetilde{\tau}}$  and  $\theta_{\widetilde{\chi}_{1}^{0}}$ 

## **Topology selection**

## Take over SPS1a' $\tilde{\tau}$ analysis principle

 $\tilde{\ell}$  properties:

- Only two particles (possibly *τ*:s:s) in the final state.
- Large missing energy and momentum.
- High Acolinearity, with little correlation to the energy of the τ decay-products.
- Central production.
- No forward-backward asymmetry.
- + anti  $\gamma\gamma$  cuts.

## Select this by:

- Exactly two jets.
- $N_{ch} < 10$
- Vanishing total charge.
- Charge of each jet =  $\pm 1$ ,
- $M_{jet} < 2.5 \, {\rm GeV}/c^2$ ,
- *E<sub>vis</sub>* significantly less than E<sub>CMS</sub>.
- *M<sub>miss</sub>* significantly less than *M<sub>CMS</sub>*.
- No particle with momentum close to E<sub>beam</sub>.

## **Topology selection**

# $\tilde{\mu}_{\rm R}$ threshold scan

From these spectra, we can estimate  $M_{\tilde{e}_R}$ ,  $M_{\tilde{\mu}_R}$  and  $M_{\tilde{\chi}_1^0}$  to < 1 GeV.

# So: Next step is $M_{\tilde{\mu}_R}$ from threshold:

• 10 points, 10 fb $^{-1}$ /point.

• Luminousity  $\propto E_{CMS}$ , so this is  $\Leftrightarrow 170 \text{ fb}^{-1} @ E_{CMS} = 500 \text{ GeV}.$ 

Error on  $M_{\tilde{\mu}_{\mathrm{R}}}$  = 197 MeV

# $\tilde{\mu}_{\rm R}$ threshold scan

From these spectra, we can estimate  $M_{\tilde{e}_R}$ ,  $M_{\tilde{\mu}_R}$  and  $M_{\tilde{\chi}_1^0}$  to < 1 GeV.

So: Next step is  $M_{\tilde{\mu}_R}$  from threshold:

- 10 points, 10 fb<sup>-1</sup>/point.
- Luminousity  $\propto E_{CMS}$ , so this is  $\Leftrightarrow$  170 fb<sup>-1</sup> @  $E_{CMS}$ =500 GeV.

Error on  $M_{\widetilde{\mu}_{
m R}}$  = 197 MeV

# $\tilde{\mu}_{\rm R}$ threshold scan

From these spectra, we can σ(e⁺e⁻→μ̃<sub>R</sub>μ̃<sub>R</sub>) [fb] estimate  $M_{\tilde{e}_{R}}$ ,  $M_{\tilde{\mu}_{R}}$  and  $M_{\tilde{\chi}_{1}^{0}}$  to < data 10 fb<sup>-1</sup> / point 1 GeV. fit to data :  $\delta M_{\tilde{i}} = 197 \text{ MeV}$ M. = 135.28 GeV So: Next step is  $M_{\tilde{\mu}_{P}}$  from 6  $M_{\tilde{u}} = 135.4 \pm 0.2 \text{ GeV}$ threshold: 5 • 10 points, 10 fb $^{-1}$ /point. • Luminousity  $\propto E_{CMS}$ , so this is 3  $\Leftrightarrow$  170 fb<sup>-1</sup> @ *E*<sub>CMS</sub>=500 GeV. 2 Error on  $M_{\tilde{\mu}_{R}} = 197 \text{ MeV}$ 0 272 274 276 278 280 282 √s [GeV]

# Outlook (STC4)

- Study edge detection in spectra with methods borrowed from image processing.
- Currently being developed for e
  <sub>R</sub> (S. Caiazza thesis). Also adopted to "Point 5" (model with on-shell IVB bosino decays).
- Make a coherent SGV study of all channels, at all *E<sub>CMS</sub>* stages.
  - Also channels not studied in SPS1a'
  - Exploit more complex decay cascades.
- All signals generated.
- Background exists, need to replicate 250 & 350 from KEK to DESY.
- Expect results with in a few months.

If indeed SUSY is kinematically accessible, the ILC is the ideal place to study it.

- Lepton-collider: Initial state is known.
- Production is EW  $\Rightarrow$ 
  - Small theoretical uncertainties.
  - No "underpaying event".
  - Low cross-sections also for background.
  - Trigger-less operation, so that even very soft stuff will be on tape.
- Many observables accessible: Spectra, angular distributions, total and differential cross-sections, branching ratios, ...
- Often measurable to per mil level.
- I've shown as an example what can be measured in the STC4 bench-mark. Please check out other cases presented this week:
  - Talks by Sert, Krücker, Kato, Mori, .... in the BSM sessions.
