## Using the Hadronic Recoil Cross Section Measurement in Higgs <br> Coupling Fits

Tim Barklow (SLAC)
Sep 08, 2014

# Mark Thomson's analysis of $\sigma(Z H)$ with $Z \rightarrow q \bar{q}$ uses two measurements to obtain the cross section: 

 $\sigma(Z H)=\sigma(Z H) \cdot B R($ visible $)+\sigma(Z H) \cdot B R($ invisible $)$$\sigma(Z H) \cdot B R($ visible $)$
Final(?) Results

| Process | $\sigma / \mathrm{fb}$ | $\varepsilon_{\text {presel }}$ | $\varepsilon_{\mathscr{L}>0.70}$ | $N_{\mathscr{L}>0.70}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $q \bar{q}$ | 25180 | 0.5\% | <0.1\% | 6211 | - signal ~9.5k events |
| $q \bar{q} 1 v$ | 5914 | 6.4\% | 0.1\% | 3895 | - background $\sim 19 \mathrm{k}$ events |
| q $\bar{q} q \bar{q}$ | 5847 | 4.2\% | 0.4\% | 10818 |  |
| q $\bar{q} 11$ | 1704 | 1.2\% | 0.1\% | 1218 |  |
| $q \bar{q} v \bar{v}$ | 325 | 0.6\% | <0.1\% | 35 | c.f. LCWS analysis |
| $\mathrm{Hv}_{\mathrm{e}} \overline{\mathrm{v}}_{\mathrm{e}}$ |  | - \% |  |  |  |
| HZ | 93.4 | 44.0\% | 20.3\% | 9493 |  |
| $\mathrm{H} \rightarrow$ invis. |  | 0.6\% | <0.1\% | - |  |
| $\mathrm{H} \rightarrow \mathrm{q} \overline{\mathrm{q}} / \mathrm{gg}$ |  | 43.5\% | 20.6\% | 6211 | Efficiencies same |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*}$ |  | 44.7\% | 19.5\% | 2240 | to ~10 \% !!! |
| $\mathrm{H} \rightarrow \mathrm{ZZ}^{*}$ |  | 40.0\% | 18.1\% | 254 |  |
| $\mathrm{H} \rightarrow \tau^{+} \tau^{-}$ |  | 47.6\% | 21.4\% | 738 |  |
| $\mathrm{H} \rightarrow \gamma \gamma$ |  | 42.8\% | 22.1\% | 32 | $\square$ aimost model |
| $\mathrm{H} \rightarrow \mathrm{Z} \gamma$ |  | 41.8\% | 17.6\% | 17 | $\checkmark$ independent |
| $\mathrm{H} \rightarrow \mu^{+} \mu^{-}$ |  | 39.5\% | 20.6\% | 3 |  |

$\sigma(Z H) \cdot B R($ invisible) BDT Selection

ћ Assuming no invisible decays (1 sigma stat. error):

$$
\Rightarrow \Delta \sigma_{\mathrm{invis}}= \pm 0.57 \%
$$

(CLIC beam spectrum, $500 \mathrm{fb}^{-1} @ 350 \mathrm{GeV}$, no polarisation)

In order to use this cross section measurement in our Higgs analyses we have to quantify the penalty associated with the fact that
$\sigma(Z H) \cdot B R(v i s i b l e)$ is "almost model independent". By how much must we blow up $\Delta \sigma(Z H) \cdot B R($ visible) to account for the fact that the efficiencies differ by $10 \%$ or more?

## Model Indepedence

* Combining visible + invisible analysis: wanted M.I.
- i.e. efficiency independent of Higgs decay mode

| Decay mode | $\varepsilon_{\mathscr{L}>0.70}^{\text {vis }}$ | $\varepsilon_{\text {BDT }}^{\text {invis }}$ i ${ }_{\text {d }}$ | $\varepsilon^{\text {vis }}+\varepsilon^{\text {invis }}$ |  |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{H} \rightarrow$ invis. | <0.1\% | 20.7 \% | 20.7 \% |  |
| $\mathrm{H} \rightarrow \mathrm{q} \overline{\mathrm{q}} / \mathrm{gg}$ | 20.6\% | <0.1\% | 20.6\% |  |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*}$ | 19.5 \% | <0.1\% | 19.8\% |  |
| $\mathrm{H} \rightarrow \mathrm{ZZ}^{*}$ | 18.1\% | 0.9 \% | 19.0\% | Very similar |
| $\mathrm{H} \rightarrow \tau^{+} \tau^{-}$ | 21.4\% | 0.1 \% | 21.5 \% | efficiencies |
| $\mathrm{H} \rightarrow \gamma \gamma$ | 22.1 \% | <0.1\% | 22.1 \% |  |
| $\mathrm{H} \rightarrow \mathrm{Z} \gamma$ | 17.6\% | <0.1\% | 17.1 \% |  |
| $\mathrm{H} \rightarrow \mu^{+} \mu^{-}$ | 20.6\% | <0.1\% | 20.6\% |  |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*} \rightarrow \mathrm{q} \overline{\mathrm{q}} \mathrm{q} \overline{\mathrm{q}}$ | 19.3\% | <0.1\% | 19.3 \% |  |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*} \rightarrow \mathrm{q} \overline{\mathrm{q}} \mathrm{lv}$ | 19.6\% | <0.1\% | 19.6\% | Look at wide |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*} \rightarrow \mathrm{q} \overline{\mathrm{q}} \tau \nu$ | 19.9 \% | <0.1\% | 19.9\% | range of WW |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*} \rightarrow \mathrm{lvlv}$ | 22.0\% | $0.3 \%$ | 22.3 \% | topologies |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*} \rightarrow \mathrm{lv} \tau \nu$ | 16.7 \% | $0.3 \%$ | 17.0\% | topologies |
| $\mathrm{H} \rightarrow \mathrm{WW}^{*} \rightarrow \tau \nu \tau \nu$ | 12.2\% | 1.3 \% | 13.6\% |  |

We have used an approach where we use all of our $\sigma \cdot B R$ measurements for visible Higgs decays to obtain an estimate of the average signal efficiency for $\sigma(\mathrm{ZH}) \cdot B R$ (visible). It is then straightforward to propagate the $\sigma \cdot B R$ errors to the error on $\sigma(Z H) \cdot B R($ visible), This means that one must take into account the correlation between the $\sigma \cdot B R$ measurements and our $\sigma(Z H)$ measurement from hadronic $Z$ decays when we fit for couplings and total width. It also means that we must develop $\sigma \cdot B R$ analyses for all possible BSM Higgs decays
$\Psi \equiv \sigma(Z H) \cdot B R$ (visible)
$\Omega=$ Number of signal + background events in $\sigma(Z H) \cdot B R($ visible $)$ analysis
$B=$ Predicted number of background events in $\sigma(Z H) \cdot B R($ visible ) analysis
$\Xi=$ Average efficiency for signal events to pass $\sigma(Z H) \cdot B R($ visible $)$ analysis
$L=$ luminosity
$\Psi=\frac{\Omega-\mathrm{B}}{L \Xi}=\frac{1}{\Xi} \sum_{i} \psi_{i} \xi_{i}=\sum_{i} \psi_{i} \quad$ where
$\psi_{i}=\sigma(Z H) \cdot B R_{i}$
$\xi_{i}=$ efficiency for events from Higgs decay $i$ to pass $\sigma(Z H) \cdot B R($ visible) analysis
$\Xi=\frac{\sum_{i} \psi_{i} \xi_{i}}{\sum_{i} \psi_{i}}$
$\psi_{i}=\frac{\omega_{i}-\beta_{i}}{L \eta_{i}}$
$\omega_{i}=$ Number of signal + background events in $\sigma(Z H) \cdot B R_{i}$ analysis
$\beta_{i}=$ Predicted number of background events in $\sigma(Z H) \cdot B R_{i}$ analysis
$\eta_{i}=$ efficiency for Higgs decay $i$ to pass $\sigma \cdot B R_{i}$ analysis
$K_{i}=$ number of signal + background events common to had $Z$ recoil and $\sigma \cdot B R_{i}$ analyses
$\mathrm{E}=$ number of signal + background events unique to had Z recoil analysis
$\varepsilon_{i}=$ number of signal + background events events unique to $\sigma \bullet B R_{i}$ analysis
$\Omega=\mathrm{E}+\sum_{i} \mathrm{~K}_{i} \quad \mathrm{~S} \equiv \Omega-\mathrm{B} \quad \mathrm{T} \equiv \frac{\sqrt{S+\mathrm{B}}}{\mathrm{S}}$
$\omega_{i}=\mathrm{K}_{i}+\varepsilon_{i} \quad s_{i} \equiv \omega_{i}-\beta_{i} \quad \tau_{i} \equiv \frac{\sqrt{\mathrm{~s}_{i}+\beta_{i}}}{\mathrm{~s}_{i}}$
$\lambda_{i} \equiv \frac{\mathrm{~K}_{i}}{\omega_{i}} \quad N \equiv L \sigma_{z H} \quad r_{i} \equiv B R_{i} \quad \delta_{i} \equiv \xi_{i}-\Xi$
$\left(\frac{\Delta \Psi}{\Psi}\right)^{2}=\mathrm{T}^{2}\left\{1+\frac{N^{2}}{\Omega} \sum_{i} r_{i}^{2} \tau_{i}^{2}\left[\delta_{i}^{2}-2 \lambda_{i} \eta_{i} \delta_{i}\right]\right\} \quad \begin{aligned} & \text { This is our result for the error on } \sigma(Z H) \cdot B R \text { (visible) } \\ & \text { given the approach outlined on page } 22\end{aligned}$

But, if we are confident in our measurement of $\sigma(Z H) \cdot B R(H \rightarrow B S M)$, why don't we simply calculate $\sigma(Z H)$ using $\sum_{i} \sigma(Z H) \cdot B R_{i} \quad$ ?

In fact this is what Michael Peskin does in his fits when he uses the constraint $\sum_{i} B R_{i}=1$. If this constraint implicitly includes an hadronic recoil ZH cross section measurement, then the importance of the leptonic recoil ZH cross section measurement should diminish when this constraint is imposed. This indeed is the case, as demonstrated in the following slides where Higgs couplings are calculated for different values of a $\Delta \sigma_{z H}$ scale factor.

## Energy Diff Lum Run Time* Int Lumi <br> $250 \mathrm{GeV} \quad 0.75 \mathrm{~cm}^{-2} \mathrm{~s}^{-1} \quad 2.4 \mathrm{yr} \quad 280 \mathrm{fb}^{1}$

| $\Gamma_{T}$ | $2.0 \%$ | $0.79 \%$ | $3.5 \%$ | $0.79 \%$ | $6.6 \%$ | $0.79 \%$ | $13 \%$ | $0.79 \%$ |

It is clear from these results that $\sigma(\mathrm{ZH})$ is being calculated implictly using $\sigma(Z H)=\sum_{i} \sigma(Z H) \cdot B R_{i}$
whenever the constraint $\sum_{i} B R_{i}=1$ is imposed.

It appears that we have no need for a separate direct hadronic ZH recoil cross section measurement once we are confident that we have $\sigma(Z H) \cdot B R(H \rightarrow$ visible $B S M)$ under control. In fact, it appears that we don't even need the classic leptonic ZH recoil cross section measurement in this case!

## Caveats:

These results assume that the true $B R(H \rightarrow B S M)=0$ and that $B R(H \rightarrow$ visible BSM $)<0.9 \%$ at $95 \%$ CL can be achieved with $\sqrt{s}=250 \mathrm{GeV} \& 250 \mathrm{fb}^{-1}$ or $\sqrt{s}=350 \mathrm{GeV} \& 500 \mathrm{fb}^{-1}$. (That is, it has been assumed that the same precision can be achieved for invisible decays and visible BSM decays.)
This has yet to be demonstrated.

Also, we have to check how these conclusions are altered if the true $B R(H \rightarrow B S M)=1 \%$, or $10 \%$.

## 215 page "Exotic Decays of the 125 GeV Higgs Boson" arXiv:1312.4992: Is this a starting point for a complete $\sigma \bullet \mathrm{BR}(H \rightarrow B S M)$ analysis?

## Questions

- What is the required precision on $\sigma \cdot B R(H \rightarrow B S M)$ if we want to impose the constraint $\sum_{i} B R_{i}=1$ ?
- What is the required precision on $\sigma \cdot B R(H \rightarrow B S M)$ if want to use the direct hadronic recoil measurement of $\sigma(Z H)$ ?
- Do the 18 different $\sigma \cdot B R\left(H \rightarrow B S M_{i}\right)$ searches outlined in arXiv:1312.4992 cover all possible BSM decays? If not, what else is needed? And once we have answered that question, how do we prove that everything has indeed been covered?

& =\frac{1}{\Omega}\left(1-\frac{\mathrm{B}}{\Omega}\right)^{-2}+\frac{1}{L^{2} \Xi^{2} \Psi^{2}} \sum_{i} \frac{\left(\xi_{i}-\Xi\right)^{2}}{\left(\eta_{i}\right)^{2}}\left(L \eta_{i} \psi_{i}+\beta_{i}\right)-\frac{2}{L \Omega \Xi \Psi}\left(1-\frac{\mathrm{B}}{\Omega}\right)^{-1} \sum_{i} \frac{\xi_{i}-\Xi}{\eta_{i}} \lambda_{i}\left(L \eta_{i} \psi_{i}+\beta_{i}\right) \\
& =\frac{1}{\Omega}\left(1-\frac{\mathrm{B}}{\Omega}\right)^{-2}\left[1+\frac{L}{\Omega} \sum_{i} \frac{\left(\xi_{i}-\Xi\right)^{2}}{\eta_{i}} \psi_{i}\left(1+\frac{\beta_{i}}{\mathrm{~S}_{i}}\right)-\frac{2 L}{\Omega} \sum_{i}\left(\xi_{i}-\Xi\right) \psi_{i} \lambda_{i}\left(1+\frac{\beta_{i}}{S_{i}}\right)\right] \\
& =\frac{S+\mathrm{B}}{S^{2}}\left\{1+\frac{L}{\Omega} \sum_{i}\left(\xi_{i}-\Xi\right) \psi_{i}\left(\frac{s_{i}+\beta_{i}}{s_{i}^{2}}\right)\left[\left(\xi_{i}-\Xi\right) L \psi_{i}-2 \lambda_{i} s_{i}\right]\right\} \\
& =\mathrm{T}^{2}\left\{1+\frac{N^{2}}{\Omega} \sum_{i} r_{i}^{2} \tau_{i}^{2}\left[\delta_{i}^{2}-2 \lambda_{i} \eta_{i} \delta_{i}\right]\right\}
\end{aligned}
$$

What if we don't do a hadronic $Z$ recoil measurement and instead only use $\sigma(Z H) \cdot B R_{i}$ to calculate $\sigma(Z H) \cdot B R($ visible $)=\sum_{i} \sigma(Z H) \cdot B R_{i}$ ?

$$
\begin{aligned}
& \Psi^{\prime}=\sum_{i} \psi_{i} \quad \psi_{i}=\frac{\omega_{i}-\beta_{i}}{L \xi_{i}} \\
& \left(\Delta \Psi^{\prime}\right)^{2}=\sum_{i}\left(\frac{\partial \Psi^{\prime}}{\partial \omega_{i}}\right)^{2} \omega_{i}, \quad \frac{\partial \Psi^{\prime}}{\partial \omega_{i}}=\frac{1}{L \eta_{i}^{\prime}} \\
& \left(\Delta \Psi^{\prime}\right)^{2}=\frac{1}{L^{2}} \sum_{i}=\frac{1}{L^{2}} \sum_{i} \frac{S_{i}+\beta_{i}}{\xi_{i}^{2}} \\
& \left(\frac{\Delta \Psi^{\prime}}{\Psi^{\prime}}\right)^{2}=\left(\sum_{i} \frac{\omega_{i}-\beta_{i}}{L \xi_{i}}\right)^{-2} \frac{1}{L^{2}} \sum_{i} \frac{S_{i}+\beta_{i}}{\xi_{i}^{2}} \\
& =\frac{S+\mathrm{B}}{S^{2}} \frac{L}{\Omega} \Xi^{2} \sum_{i} \frac{\psi_{i}}{\xi_{i}}\left(1+\frac{\beta_{i}}{S_{i}}\right)
\end{aligned}
$$

Compare this now with our formula for $\left(\frac{\Delta \Psi}{\Psi}\right)^{2}$ for $\lambda_{i}=1$ :

$$
\begin{aligned}
\left(\frac{\Delta \Psi}{\Psi}\right)^{2} & =\frac{S+\mathrm{B}}{S^{2}}\left\{1+\frac{1}{\Omega} \sum_{i} \omega_{i}\left[\left(1-\frac{\Xi}{\xi_{i}}\right)^{2}-2\left(1-\frac{\Xi}{\xi_{i}}\right)\right]\right\} \\
& =\frac{S+\mathrm{B}}{S^{2}}\left\{1+\frac{1}{\Omega} \sum_{i} \omega_{i}\left[1-\frac{2 \Xi}{\xi_{i}}+\left(\frac{\Xi}{\xi_{i}}\right)^{2}-2+2 \frac{\Xi}{\xi_{i}}\right]\right\}=\left(\frac{\Delta \Psi^{\prime}}{\Psi^{\prime}}\right)^{2}
\end{aligned}
$$
